  15.8. Display Configuration ............................................................................... 189
  15.9. Package Selection ..................................................................................... 190
Preface

1. Document Conventions

This manual uses several conventions to highlight certain words and phrases and draw attention to specific pieces of information.

In PDF and paper editions, this manual uses typefaces drawn from the Liberation Fonts\(^1\) set. The Liberation Fonts set is also used in HTML editions if the set is installed on your system. If not, alternative but equivalent typefaces are displayed. Note: Red Hat Enterprise Linux 5 and later includes the Liberation Fonts set by default.

1.1. Typographic Conventions

Four typographic conventions are used to call attention to specific words and phrases. These conventions, and the circumstances they apply to, are as follows.

**Mono-spaced Bold**

Used to highlight system input, including shell commands, file names and paths. Also used to highlight keycaps and key combinations. For example:

To see the contents of the file *my_next_bestselling_novel* in your current working directory, enter the `cat my_next_bestselling_novel` command at the shell prompt and press *Enter* to execute the command.

The above includes a file name, a shell command and a keycap, all presented in mono-spaced bold and all distinguishable thanks to context.

Key combinations can be distinguished from keycaps by the hyphen connecting each part of a key combination. For example:

Press *Enter* to execute the command.

Press *Ctrl+Alt+F2* to switch to the first virtual terminal. Press *Ctrl+Alt+F1* to return to your X-Windows session.

The first paragraph highlights the particular keycap to press. The second highlights two key combinations (each a set of three keycaps with each set pressed simultaneously).

If source code is discussed, class names, methods, functions, variable names and returned values mentioned within a paragraph will be presented as above, in **mono-spaced bold**. For example:

File-related classes include *filesystem* for file systems, *file* for files, and *dir* for directories. Each class has its own associated set of permissions.

**Proportional Bold**

This denotes words or phrases encountered on a system, including application names; dialog box text; labeled buttons; check-box and radio button labels; menu titles and sub-menu titles. For example:

Choose *System* → *Preferences* → *Mouse* from the main menu bar to launch *Mouse Preferences*. In the *Buttons* tab, click the *Left-handed mouse* check box and click

---

\(^1\) [https://fedorahosted.org/liberation-fonts/](https://fedorahosted.org/liberation-fonts/)
Close to switch the primary mouse button from the left to the right (making the mouse suitable for use in the left hand).

To insert a special character into a gedit file, choose Applications → Accessories → Character Map from the main menu bar. Next, choose Search → Find… from the Character Map menu bar, type the name of the character in the Search field and click Next. The character you sought will be highlighted in the Character Table. Double-click this highlighted character to place it in the Text to copy field and then click the Copy button. Now switch back to your document and choose Edit → Paste from the gedit menu bar.

The above text includes application names; system-wide menu names and items; application-specific menu names; and buttons and text found within a GUI interface, all presented in proportional bold and all distinguishable by context.

Mono-spaced Bold Italic or Proportional Bold Italic

Whether mono-spaced bold or proportional bold, the addition of italics indicates replaceable or variable text. Italics denotes text you do not input literally or displayed text that changes depending on circumstance. For example:

To connect to a remote machine using ssh, type ssh username@domain.name at a shell prompt. If the remote machine is example.com and your username on that machine is john, type ssh john@example.com.

The mount -o remount file-system command remounts the named file system. For example, to remount the /home file system, the command is mount -o remount /home.

To see the version of a currently installed package, use the rpm -q package command. It will return a result as follows: package-version-release.

Note the words in bold italics above — username, domain.name, file-system, package, version and release. Each word is a placeholder, either for text you enter when issuing a command or for text displayed by the system.

Aside from standard usage for presenting the title of a work, italics denotes the first use of a new and important term. For example:

Publican is a DocBook publishing system.

1.2. Pull-quote Conventions

Terminal output and source code listings are set off visually from the surrounding text.

Output sent to a terminal is set in mono-spaced roman and presented thus:

```
books        Desktop   documentation  drafts  mss    photos   stuff  svn
books_tests  Desktop1  downloads      images  notes  scripts  svgs
```

Source-code listings are also set in mono-spaced roman but add syntax highlighting as follows:

```
package org.jboss.book.jca.ex1;
import javax.naming.InitialContext;
```
public class ExClient {
    public static void main(String args[])
        throws Exception {
        InitialContext iniCtx = new InitialContext();
        Object ref = iniCtx.lookup("EchoBean");
        EchoHome home = (EchoHome) ref;
        Echo echo = home.create();
        System.out.println("Created Echo");
        System.out.println("Echo.echo('Hello') = " + echo.echo("Hello"));
    }
}

1.3. Notes and Warnings
Finally, we use three visual styles to draw attention to information that might otherwise be overlooked.

💡 **Note**

Notes are tips, shortcuts or alternative approaches to the task at hand. Ignoring a note should have no negative consequences, but you might miss out on a trick that makes your life easier.

🌟 **Important**

Important boxes detail things that are easily missed: configuration changes that only apply to the current session, or services that need restarting before an update will apply. Ignoring a box labeled 'Important' will not cause data loss but may cause irritation and frustration.

⚠️ **Warning**

Warnings should not be ignored. Ignoring warnings will most likely cause data loss.

2. We Need Feedback!

If you find a typographical error in this manual, or if you have thought of a way to make this manual better, we would love to hear from you! Please submit a report in Bugzilla: [http://bugzilla.redhat.com/bugzilla/](http://bugzilla.redhat.com/bugzilla/) against the product Fedora Documentation.

When submitting a bug report, be sure to mention the manual’s identifier: install-guide

If you have a suggestion for improving the documentation, try to be as specific as possible when describing it. If you have found an error, please include the section number and some of the surrounding text so we can find it easily.

3. Acknowledgements

Introduction

This guide covers installation of Fedora, a Linux distribution built on free and open source software. This manual helps you install Fedora on desktops, laptops, and servers. The installation system is easy to use even if you lack previous knowledge of Linux or computer networks. If you select default options, Fedora provides a complete desktop operating system, including productivity applications, Internet utilities, and desktop tools.

This document details the full range of installation options, including those that apply only in limited or unusual circumstances. The **Fedora 14 Installation Quick Start Guide** provides a much-abbreviated set of instructions for downloading Fedora, creating an installation disc, and installing Fedora on a typical desktop or laptop computer. The **Fedora 14 Installation Quick Start Guide** is available from [http://docs.fedoraproject.org/installation-quick-start-guide/](http://docs.fedoraproject.org/installation-quick-start-guide/).

1. Background

1.1. About Fedora

To find out more about Fedora, refer to [http://fedoraproject.org/](http://fedoraproject.org/). To read other documentation on Fedora related topics, refer to [http://docs.fedoraproject.org/](http://docs.fedoraproject.org/).

1.2. Getting Additional Help

For information on additional help resources for Fedora, visit [http://fedoraproject.org/wiki/Communicate](http://fedoraproject.org/wiki/Communicate).

2. About This Document

2.1. Goals

This guide helps a reader:

1. Understand how to locate the Fedora distribution online
2. Create configuration data that allows a computer to boot Fedora
3. Understand and interact with the Fedora installation program
4. Complete basic post-installation configuration of a Fedora system

Other Sources of Documentation

This guide does not cover use of Fedora. To learn how to use an installed Fedora system, refer to [http://docs.fedoraproject.org/](http://docs.fedoraproject.org/) for other documentation.

2.2. Audience

This guide is intended for Fedora users of all levels of experience. However, it treats the installation process and its many options in far greater detail than most novice users are likely to require. You do not need to read and understand this entire document to install Fedora on a computer. This document is most likely to help experienced users perform advanced and unusual installations.
Quick Start for Experts

This section offers a very brief overview of installation tasks for experienced readers who are eager to get started. Note that many explanatory notes and helpful hints appear in the following chapters of this guide. If an issue arises during the installation process, consult the appropriate chapters in the full guide for help.

Experts Only

This section is intended only for experts. Other readers may not be familiar with some of the terms in this section, and should move on to Chapter 2, Obtaining Fedora instead.

1.1. Overview

The installation procedure is fairly simple, and consists of only a few steps:

1. Download files to make media or another bootable configuration.
2. Prepare system for installation.
3. Boot the computer and run the installation process.
4. Reboot and perform post-installation configuration.

1.2. Download Files

Do any one of the following:

Verify your downloads

Downloads may fail for any number of reasons. Always verify the sha256sum of the downloaded files.

1. Download the ISO image for a Live image. Create CD media from the ISO file using your preferred application. You may also use the livecd-tools package to write the image to other bootable media such as a USB flash disk. To install the distribution to your hard disk, use the shortcut on the desktop after you log in.

2. Download the ISO images for the full distribution on CD or DVD. Create CD or DVD media from the ISO files using your preferred application, or put the images on a Windows FAT32 or Linux ext2, ext3, or ext4 partition.

3. Download the boot.iso image for a minimal boot CD or USB flash drive. Write the image to the appropriate physical media to create bootable media. The boot media contains no packages but must be pointed at a hard disk or online repository to complete the installation.

4. Download the vmlinuz kernel file and the initrd.img ramdisk image from the distribution's isolinux/ directory. Configure your operating system to boot the kernel and load the ramdisk image. For further information on installation without media, refer to Chapter 11, Installing Without Media.

For information on setting up a network boot server from which you can install Fedora, refer to Chapter 12, Setting Up an Installation Server.
To learn how to turn ISO images into CD or DVD media, refer to *Making Fedora Discs* available from http://docs.fedoraproject.org/readme-burning-isos/.

### 1.3. Prepare for Installation

Back up any user data you need to preserve.

**Resizing Partitions**

The installation program provides functions for resizing ext2, ext3, ext4, and NTFS formatted partitions. Refer to *Section 8.17, “Creating a Custom Layout or Modifying the Default Layout”* for more information.

### 1.4. Install Fedora

Boot from the desired media, with any options appropriate for your hardware and installation mode. Refer to *Chapter 10, Boot Options* for more information about boot options. If you boot from the Live CD, select the "Install to Hard Disk" option from the desktop to run the installation program. If you boot from minimal media or a downloaded kernel, select a network or hard disk resource from which to install.

Proceed through all the steps of the installation program. The installation program does not change your system until you make a final confirmation to proceed. When installation is finished, reboot your system.

### 1.5. Perform Post-installation Steps

After the system reboots, it displays additional configuration options. Make appropriate changes to your system and proceed to the login prompt.

Refer to *Chapter 16, Firstboot* or the Firstboot page on the Fedora wiki: http://fedoraproject.org/wiki/FirstBoot for more detail.
Part I. Preparing for Installation

This part of the Fedora Installation Guide covers decisions that you should make and resources that you should gather before installing Fedora, including:

- the decision whether to upgrade an existing installation of Fedora or install a new copy.
- hardware considerations, and hardware details that you may need during installation.
Obtaining Fedora

This chapter explains how to get the files you need to install and run Fedora on your computer. Concepts in this chapter may be new, especially if this is your first free and open source operating system. If you have any trouble with this chapter, find help by visiting the Fedora Forums at http://www.fedoraforum.org/.

The Fedora Project distributes Fedora in many ways, mostly free of cost and downloaded over the Internet. The most common distribution method is CD and DVD media. There are several types of CD and DVD media available, including:

- A full set of the software on DVD media
- Live images you can use to try Fedora, and then install to your system if you so choose
- Reduced-size bootable CD and USB flash disk images you can use to install over an Internet connection
- Source code on DVD media

Most users want the Fedora Live image or the full set of installable software on DVD or CDs. The reduced bootable images are suitable for use with a fast Internet connection and install Fedora on one computer. Source code discs are not used for installing Fedora, but are resources for experienced users and software developers.

Users with a broadband Internet connection can download ISO images of CD and DVD media or images of USB flash disks. An ISO image is a copy of an entire disc in a format suitable for writing directly to a CD or DVD. A USB flash disk image is a copy of an entire disk in a format suitable for writing directly to a USB flash disk.

For more information on burning CDs and DVDs, refer to Chapter 3, Making Media.

If downloading the Fedora ISO images and burning them to CD or DVD is impossible or impractical for you, refer to Section 2.2, “Obtaining Fedora on CD or DVD” to learn about other ways that you can obtain Fedora.

2.1. Downloading Fedora

2.1.1. How Do I Download Installation Files?

Download Links

To follow a Web-based guide to downloading, visit http://get.fedoraproject.org/. For guidance on which architecture to download, refer to Section 2.1.2, “Which Architecture Is My Computer?”.

Fedora software is available for download at no cost in a variety of ways.

2.1.1.1. From a Mirror

The Fedora installation files are freely available from web servers located in many parts of the world. These servers mirror the files available from the Fedora Project. If you visit http://
download.fedoraproject.org/, you are redirected to a mirror, based on a calculation of which mirror is likely to offer you the best download speed. Alternatively, you can choose a mirror from the list maintained at http://mirrors.fedoraproject.org/publiclist. This page lists mirrors according to geographic location. The mirrors geographically closest to you are likely to provide you with the fastest downloads. If the company or organization that provides your internet access maintains a mirror, this mirror is likely to provide you with the fastest downloads of all.

Mirrors publish Fedora software under a well-organized hierarchy of folders. For example, the Fedora 14 distribution normally appears in the directory fedora/linux/releases/14/. This directory contains a folder for each architecture supported by that release of Fedora. CD and DVD media files appear inside that folder, in a folder called iso/. For example, you can find the file for the DVD distribution of Fedora 14 for x86_64 at fedora/linux/releases/14/Fedora/x86_64/iso/Fedora-14-x86_64-DVD.iso.

2.1.1.2. From BitTorrent
BitTorrent is a way to download information in cooperation with other computers. Each computer cooperating in the group downloads pieces of the information in a particular torrent from other peers in the group. Computers that have finished downloading all the data in a torrent remain in the swarm to seed, or provide data to other peers. If you download using BitTorrent, as a courtesy you should seed the torrent at least until you have uploaded the same amount of data you downloaded.

If your computer does not have software installed for BitTorrent, visit the BitTorrent home page at http://www.bittorrent.com/download/ to download it. BitTorrent client software is available for Windows, Mac OS, Linux, and many other operating systems.

You do not need to find a special mirror for BitTorrent files. The BitTorrent protocol ensures that your computer participates in a nearby group. To download and use the Fedora BitTorrent files, visit http://torrent.fedoraproject.org/.

Minimal Boot Images

Minimal boot CD and USB flash disk images are not available through BitTorrent.

2.1.2. Which Architecture Is My Computer?
Releases are separated by architecture, or type of computer processor. Use the following table to determine the architecture of your computer according to the type of processor. Consult your manufacturer's documentation for details on your processor, if necessary.

<table>
<thead>
<tr>
<th>Processor manufacturer and model</th>

Which Files Do I Download?

**i386 Works for Most Windows Compatible Computers**

If you are unsure what type of processor your computer uses, choose i386.

The exception is if your computer is a non-Intel based Apple Macintosh. Refer to Table 2.1, “Processor and architecture types” for more information.

**Intel Atom Processor Architectures Vary**

### 2.1.3. Which Files Do I Download?

You have several options to download Fedora. Read the options below to decide the best one for you.

Each file available for download in a Fedora distribution includes the architecture type in the file name. For example, the file for the DVD distribution of Fedora 14 for x86_64 is named **Fedora-14-x86_64-DVD.iso**. Refer to Section 2.1.2, “Which Architecture Is My Computer?” if you are unsure of your computer’s architecture.

**Full Distribution on DVD**

If you have plenty of time, a fast Internet connection, and wish a broader choice of software on the install media, download the full DVD version. Once burned to DVD, the media is bootable and includes an installation program. The DVD version contains a mode to perform rescue operations on your Fedora system in an emergency. You can download the DVD version directly from a mirror, or via BitTorrent.

**Full Distribution on a set of CDs**

If the DVD image is too large for you to download conveniently, or you want to have a broad choice of software to install on a system with a CD drive but no DVD drive, you can download the full distribution as a set of CDs. The total size of the images that make up the CD set is approximately the same as the size of the DVD image. You can download the images that make up the CD set directly from a mirror, or via BitTorrent.

**Live Image**

If you want to try Fedora before you install it on your computer, download the Live image version. If your computer supports booting from CD or USB, you can boot the operating system without making any changes to your hard disk. The Live image also provides an **Install to Hard Disk** desktop shortcut. If you decide you like what you see, and want to install it, simply activate the selection to copy Fedora to your hard disk. You can download the Live image directly from a mirror, or using BitTorrent.

**Minimal Boot Media**

If you have a fast Internet connection but do not want to download the entire distribution, you can download a small boot image. Fedora offers images for a minimal boot environment on CD. Once you boot your system with the minimal media, you can install Fedora directly over the Internet. Although this method still involves downloading a significant amount of data over the Internet, it is almost always much less than the size of the full distribution media. Once you have finished installation, you can add or remove software to your system as desired.
Chapter 2. Obtaining Fedora

Download Size

Installing the default software for Fedora over the Internet requires more time than the Live image, but less time than the entire DVD distribution. Actual results depend on the software you select and network traffic conditions.

The following table explains where to find the desired files on a mirror site. Replace arch with the architecture of the computer being installed.

<table>
<thead>
<tr>
<th>Media type</th>

</tbody>
</table>

2.2. Obtaining Fedora on CD or DVD

If you do not have a fast Internet connection, or if you have a problem creating boot media, downloading may not be an option. Fedora DVD and CD distribution media is available from a number of online sources around the world at a minimal cost. Use your favorite Web search engine to locate a vendor, or refer to http://fedoraproject.org/wiki/Distribution.
Making Media

Use the methods described in this section to create the following types of installation and boot media:

- an installation DVD
- an set of installation CDs
- a USB flash drive to use as an installation source
- a minimal boot CD or DVD that can boot the installer
- a USB flash drive to boot the installer

The following table indicates the types of boot and installation media available for different architectures and notes the image file that you need to produce the media.

<table>
<thead>
<tr>
<th>Architecture</th>

</table>

3.1. Making an installation CD set or DVD

You can make an installation CD set or DVD using the disc burning software on your computer.

The exact series of steps that produces a CD or DVD from an ISO image file varies greatly from computer to computer, depending on the operating system and disc burning software installed. Use this procedure as a general guide. You might be able to omit certain steps on your computer, or might have to perform some of the steps in a different order from the order described here.

Make sure that your disc burning software is capable of burning discs from image files. Although this is true of most disc burning software, exceptions exist.

In particular, note that the disc burning feature built into Windows XP and Windows Vista cannot burn DVDs; and that earlier Windows operating systems did not have any disc burning capability installed by default at all. Therefore, if your computer has a Windows operating system prior to Windows 7 installed on it, you need a separate piece of software for this task. Examples of popular disc burning
software for Windows that you might already have on your computer include Nero Burning ROM and Roxio Creator.

The Disk Utility software installed by default with Mac OS X on Apple computers has the capability to burn discs from images built into it already. Most widely-used CD burning software for Linux, such as Brasero and K3b, also includes this capability.

1. Download an ISO image file of a Fedora 14 disc as described in Chapter 2, Obtaining Fedora.

2. Insert a blank, writeable disc into your computer’s disc burner. On some computers, a window opens and displays various options when you insert the disc. If you see a window like this, look for an option to launch your chosen disc burning program. If you do not see an option like this, close the window and launch the program manually.

3. Launch your disc burning program. On some computers, you can do this by right-clicking (or control-clicking) on the image file and selecting a menu option with a label like Copy image to CD, or Copy CD or DVD image. Other computers might provide you with a menu option to launch your chosen disc burning program, either directly or with an option like Open With. If none of these options are available on your computer, launch the program from an icon on your desktop, in a menu of applications such as the Start menu on Windows operating systems, or in the Mac Applications folder.

4. In your disc burning program, select the option to burn a CD from an image file. For example, in Nero Burning ROM, this option is called Burn Image and is located on the File menu.

   Note that you can skip this step when using certain CD burning software; for example, Disk Utility on Mac OS X does not require it.

5. Browse to the ISO image file that you downloaded previously and select it for burning.

6. Click the button that starts the burning process.

   On some computers, the option to burn a disc from an ISO file is integrated into a context menu in the file browser. For example, when you right-click an ISO file on a computer with a Linux or UNIX operating system that runs the GNOME desktop, the Nautilus file browser presents you with the option to Write to disk.

### 3.2. Preparing a USB flash drive as an installation source

#### Unusual USB Media

In a few cases with oddly formatted or partitioned USB media, image writing may fail.

You can install Fedora on 32-bit x86 systems and BIOS-based AMD64 and Intel 64 systems using a USB flash drive, provided that your hardware supports booting from this type of device. Note that you cannot install Fedora on UEFI-based AMD64 and Intel 64 systems from a USB flash drive, although you can use a USB flash drive to boot the Fedora installer on UEFI-based AMD64 and Intel 64 systems — refer to Section 3.3, “Making Minimal Boot Media”.
3.2.1. Making Fedora USB Media on a Windows Operating System

This method is not destructive, so existing data on the media is not harmed. Nevertheless, it is always a good idea to back up important data before performing sensitive disk operations.

The most straightforward way to place a Fedora image on USB media using a Windows operating system is to transfer the Fedora live image to the USB device with the LiveUSB Creator tool.

Note that the `dd` tool discussed in Section 3.2.2, “Making Fedora USB Media in UNIX, Linux, and Similar Operating Systems” is also available for Windows. Follow the instructions in that section to use an implementation of `dd` for Windows operating systems. The instructions in this section assume that you will use LiveUSB Creator.

2. LiveUSB Creator can create live USB media either from an image file that you downloaded previously, as described in Section 2.1.3, “Which Files Do I Download?”, or it can download an image file from the Internet. Either:
   * click the Browse button under the Use existing LiveCD label, browse to the location where you previously downloaded a Fedora Live ISO file, and select that file.
   * select a Fedora Live ISO file from the drop-down menu that LiveUSB Creator presents under the Download Fedora label. Note that image files are large and that it is probably impractical to use LiveUSB Creator to download an image file if you do not have a broadband connection to the Internet.

3. Click Create Live USB.

3.2.2. Making Fedora USB Media in UNIX, Linux, and Similar Operating Systems

A graphical tool is available to create Fedora USB media on systems that run Fedora, Red Hat Enterprise Linux, or operating systems derived from either of these. To create Fedora USB media on other UNIX or Linux operating systems (including Mac OS X), use the command-line method described in Section 3.2.2.1.3, “Making Fedora USB Media with dd”.

3.2.2.1. Creating Fedora USB Media in Fedora, Red Hat Enterprise Linux, and similar Linux distributions

Graphical and command-line tools are available to create Fedora USB media on computers that run Fedora, Red Hat Enterprise Linux, and Linux distributions derived from Red Hat Enterprise Linux. The graphical tool and the works only with the Fedora live image. To create Fedora USB media from the distribution image or minimal boot media image, use the command-line method described in Section 3.2.2.1.3, “Making Fedora USB Media with dd”.

3.2.2.1.1. Making Fedora USB Media with a graphical tool

**Important — Enable Extra Packages for Enterprise Linux**

To perform this procedure on Red Hat Enterprise Linux and Linux distributions derived from it, enable the Extra Packages for Enterprise Linux (EPEL) repository. Refer to [http://fedoraproject.org/wiki/EPEL/FAQ#howtouse](http://fedoraproject.org/wiki/EPEL/FAQ#howtouse) for instructions.

**Note — This Method Is Not Destructive**

This method is not destructive, so existing data on the media is not harmed. Nevertheless, it is always a good idea to back up important data before performing sensitive disk operations.

1. Install the `liveusb-creator` on your system with your graphical package manager, or the following command:

   ```bash
   su -c 'yum -y install liveusb-creator'
   ```

2. Plug in your USB media.

3. Launch `LiveUSB Creator`, either from a menu or by entering `liveusb-creator` on the command line. Enter the root password for your system when `LiveUSB Creator` prompts you for it.

4. `LiveUSB Creator` can create live USB media either from an image file that you downloaded previously, as described in Section 2.1.3, “Which Files Do I Download?”, or it can download an image file from the Internet. Either:
   - click the `Browse` button under the **Use existing LiveCD** label, browse to the location where you previously downloaded a Fedora Live ISO file, and select that file.
   - select a Fedora Live ISO file from the drop-down menu that `LiveUSB Creator` presents under the **Download Fedora** label. Note that image files are large and that it is probably impractical to use `LiveUSB Creator` to download an image file if you do not have a broadband connection to the Internet.

5. Click **Create Live USB**.

### 3.2.2.1.2. Making Fedora USB Media with `livecd-tools`

**Important — Enable Extra Packages for Enterprise Linux**

To perform this procedure on Red Hat Enterprise Linux and Linux distributions derived from it, enable the Extra Packages for Enterprise Linux (EPEL) repository. Refer to [http://fedoraproject.org/wiki/EPEL/FAQ#howtouse](http://fedoraproject.org/wiki/EPEL/FAQ#howtouse) for instructions.
Note — This Method Is Not Destructive

This method is not destructive, so existing data on the media is not harmed. Nevertheless, it is always a good idea to back up important data before performing sensitive disk operations.

1. Install the `livecd-tools` package on your system with your graphical package manager, or the following command:

   ```
   su -c 'yum -y install livecd-tools'
   ```

2. Plug in your USB media.

3. Find the device name for your USB media. If the media has a volume name, look up the name in `/dev/disk/by-label`, or use the `findfs`:

   ```
   su -c 'findfs LABEL="MyLabel"'
   ```

   If the media does not have a volume name, or you do not know it, consult the `/var/log/messages` log for details:

   ```
   su -c 'less /var/log/messages'
   ```

4. Use the `livecd-iso-to-disk` command to write the ISO image to the media:

   ```
   su -c 'livecd-iso-to-disk the_image.iso /dev/sdX1'
   ```

   Replace `sdX1` with the device name for the partition on the USB media. Most flash drives and external hard disks use only one partition. If you have changed this behavior or have oddly partitioned media, you may need to consult other sources of help.

3.2.2.1.3. Making Fedora USB Media with dd

Warning — These instructions could destroy data

When you perform this procedure any data on the USB flash drive is destroyed with no warning. Make sure that you specify the correct USB flash drive, and make sure that this flash drive does not contain any data that you want to keep.

1. Plug in your USB flash drive.

2. Find the device name for your USB flash drive. If the flash drive has a volume name, look up the name in `/dev/disk/by-label`, or use `findfs`:

   ```
   su -c 'findfs LABEL="MyLabel"'
   ```

   If the media does not have a volume name, or you do not know it, run `dmesg` after you connect the USB flash drive. The device name, similar to `/dev/sdc`, appears in several lines towards the end of the output.
Chapter 3. Making Media

3. Use the `dd` command to transfer the ISO image to the USB device:

```bash
dd if=path/image_name.iso of=device
```

where `path/image_name.iso` is the ISO image file of the installation DVD that you downloaded from the Red Hat Customer Portal and `device` is the USB flash drive. For example:

```bash
dd if=/Download/F14-Server-i386-DVD.iso of=/dev/sdc
```

### 3.2.2.2. Making Fedora USB Media in other Linux Distributions

To create Fedora USB media on a computer that uses a Linux distribution other than Fedora, Red Hat Enterprise Linux, and those derived from Red Hat Enterprise Linux, use one of the command-line procedures detailed in this section.

#### 3.2.2.2.1. Making Fedora USB Media with livecd-tools

**Note — This Method Is Not Destructive**

This method is not destructive, so existing data on the media is not harmed. Nevertheless, it is always a good idea to back up important data before performing sensitive disk operations.

This method works only with the Fedora live image, and only on Linux operating systems.

1. Download a live ISO file for Fedora as shown in Section 2.1.3, “Which Files Do I Download?”

2. Plug in your USB media.

3. Find the device name for your USB media. If the media has a volume name, look up the name in `/dev/disk/by-label`, or use the `findfs`:

```bash
su -c 'findfs LABEL="MyLabel"
```

If the media does not have a volume name, or you do not know it, consult the `/var/log/messages` log for details:

```bash
su -c 'less /var/log/messages'
```

4. Many Linux distributions automatically `mount` USB media devices when you connect the device to your computer. If this is the case, unmount the device. The specific method to do this varies widely between Linux distributions and desktops. Some common methods include:

   - select `File > Unmount` if the operating system presents you with a window that displays the contents of the device.
   - right-click on an icon of the device and click `Unmount`.
   - click on an icon that represents ejecting the media — commonly, an upward-pointing triangle.

5. At a command line, type `su` - to become root, and enter the root password when your system prompts you.
6. Create a *mount point* for the live image that you downloaded. For example, to use `/tmp/livecd` as the mount point, type `mkdir /tmp/livecd` and press **Enter**.

7. Mount the live image with the following command: `mount -o loop /path/to/image/file/imagefile.iso /path/to/mount/point`, where `/path/to/image/file` is the location of the image file that you downloaded, `imagefile.iso` is the image file, and `/path/to/mount/point` is the mount point that you just created.

8. Change directory to the **LiveOS** directory of the image that you just mounted. For example, `cd /tmp/livecd/LiveOS`.

9. Run the following command: `.livecd-iso-to-disk /path/to/image/file/imagefile.iso device`, where `/path/to/image/file` is the location of the image file that you downloaded, `imagefile.iso` is the image file, and `device` is the USB media device.

---

**Example 3.1. Mounting a Fedora live image file and using livecd-iso-to-disk to create live USB media**

You have downloaded a Fedora live image, **Fedora-14-i686-Live.iso**, to a folder named **Downloads** in your home directory. You have a USB flash drive plugged into your computer, named `/dev/sdc1`.

Become root:

```bash
su -
```

Make a mount point for the image:

```bash
mkdir /mnt/livecd
```

Mount the image:

```bash
mount -o loop /home/Username/Downloads/Fedora-14-i686-Live.iso /mnt/livecd
```

Change into the **LiveOS** directory of the live CD image:

```bash
cd /mnt/livecd/LiveOS
```

Run **livecd-iso-to-disk** to transfer the live image to your flash drive and make the flash drive bootable:

```bash
./livecd-iso-to-disk /home/Username/Downloads/Fedora-14-i686-Live.iso /dev/sdc1
```

---

**3.2.2.2.2. Making Fedora USB Media with dd**

⚠️ **Warning — These instructions could destroy data**

When you perform this procedure any data on the USB flash drive is destroyed with no warning. Make sure that you specify the correct USB flash drive, and make sure that this flash drive does not contain any data that you want to keep.
Chapter 3. Making Media

Use this method for the distribution image, the minimal boot media image, or on systems with a UNIX operating system (including Mac OS X).

1. Plug in your USB flash drive.

2. Find the device name for your USB flash drive. If the flash drive has a volume name, look up the name in /dev/disk/by-label, or use findfs:

   ```bash
   su -c 'findfs LABEL="MyLabel"'
   ``

   If the media does not have a volume name, or you do not know it, run dmesg after you connect the USB flash drive. The device name, similar to /dev/sdc, appears in several lines towards the end of the output.

3. Use the dd command to transfer the ISO image to the USB device:

   ```bash
   dd if=path/image_name.iso of=device
   ``

   where path/image_name.iso is the ISO image file of the installation DVD that you downloaded from the Red Hat Customer Portal and device is the USB flash drive. For example:

   ```bash
   dd if=~/Download/F14-Server-i386-DVD.iso of=/dev/sdc
   ```

3.3. Making Minimal Boot Media

A piece of minimal boot media is a CD, DVD, or USB flash drive that contains the software to boot the system and launch the installation program, but which does not contain the software that must be transferred to the system to create a Fedora installation.

Use minimal boot media:

- to boot the system to install Fedora over a network
- to boot the system to install Fedora from a hard drive
- to use a kickstart file during installation (refer to Section 14.8.1, “Creating Kickstart Boot Media”
- to commence a network or hard-drive installation or to use an anaconda update or a kickstart file with a DVD installation.

You can use minimal boot media to start the installation process on 32-bit x86 systems, AMD64 or Intel 64 systems, and POWER systems. The process by which you create minimal boot media for systems of these various types is identical except in the case of AMD64 and Intel 64 systems with UEFI firmware interfaces — refer to Section 3.3.1, “UEFI-based systems”.

To make minimal boot media for 32-bit x86 systems, BIOS-based AMD64 or Intel 64 systems, and POWER systems:

1. Download the ISO image file named boot.iso that is available at the same location as the images of the Fedora 14 installation DVD — refer to Chapter 2, Obtaining Fedora.

2. Burn boot.iso to a blank CD or DVD using the same procedure detailed in Section 3.1, “Making an installation CD set or DVD” for the installation disc, or transfer the boot.iso file to a USB device with the dd command as detailed in Section 3.2, “Preparing a USB flash drive as an installation source”. As the boot.iso file is only around 200 MB in size, you do not need an especially large USB flash drive.
3.3.1. UEFI-based systems

The Fedora Project does not provide an image to produce minimal boot CDs or DVDs for UEFI-based systems. Use a USB flash drive (as described in this section) to boot the Fedora 14 installer, or use the installation DVD with the `linux askmethod` option to boot the installer from DVD and continue installation from a different installation source — refer to Section 4.5, “Selecting an Installation Method”.

Use the `efidisk.img` file in the `images/` directory on the Fedora 14 installation DVD to produce a bootable USB flash drive for UEFI-based systems.

1. Download an ISO image file of the Fedora 14 installation DVD as described in Chapter 2, Obtaining Fedora.

2. Become root:

   ```
   su -
   ```

3. Create a mount point for the ISO image file:

   ```
   mkdir /mnt/dvdiso
   ```

4. Mount the image file:

   ```
   mount DVD.iso /mnt/dvdiso -o loop
   ```

   Where `DVD.iso` is the name of the ISO image file, for example `F14-Server-x86_64-DVD.iso`.

5. Transfer `efidisk.img` from the ISO image file to your USB flash drive:

   ```
   dd if=/mnt/dvdiso/images/efidisk.img of=/dev/device_name
   ```

   For example:

   ```
   dd if=/mnt/dvdiso/images/efidisk.img of=/dev/sdc
   ```

6. Unmount the ISO image file:

   ```
   umount /mnt/dvdiso
   ```
Part II. The installation process

This part of the *Fedora Installation Guide* details the installation process itself, from various methods of booting the installer up to the point where the computer must restart to finalize the installation. This part of the manual also includes a chapter on troubleshooting problems with the installation process.
Planning for Installation on the x86 Architecture

4.1. Upgrade or Install?
For information to help you determine whether to perform an upgrade or an installation refer to Chapter 19, Upgrading Your Current System.

4.2. Is Your Hardware Compatible?
Hardware compatibility is particularly important if you have an older system or a system that you built yourself. Fedora 14 should be compatible with most hardware in systems that were factory built within the last two years. However, hardware specifications change almost daily, so it is difficult to guarantee that your hardware is 100% compatible.

The most recent list of supported hardware can be found in the Release Notes for Fedora 14, available at http://docs.fedoraproject.org/release-notes.

At the end of a successful Fedora installation process, the installation program offers you the option to provide details of your hardware configuration anonymously to the Fedora Project (refer to Section 16.4, “Hardware Profile”). You can view the statistics gathered by this method at http://smolt.fedoraproject.org/static/stats/devices.html. Viewing the list of hardware that makes up systems on which other people have successfully installed Fedora might help you determine how suitable your hardware is.

You can also refer to the Red Hat Hardware Compatibility List, available online at:
http://hardware.redhat.com/hcl/

4.3. RAID and Other Disk Devices

**Important — Systems with Intel BIOS RAID sets**

Fedora 14 uses **mdraid** instead of **dmraid** for installation onto Intel BIOS RAID sets. These sets are detected automatically, and devices with Intel ISW metadata are recognized as mdraid instead of dmraid. Note that the device node names of any such devices under **mdraid** are different from their device node names under **dmraid**. Therefore, special precautions are necessary when you migrate systems with Intel BIOS RAID sets.

Local modifications to **/etc/fstab**, **/etc/crypttab** or other configuration files which refer to devices by their device node names will not work in Fedora 14. Before migrating these files, you must therefore edit them to replace device node paths with device UUIDs instead. You can find the UUIDs of devices with the **blkid** command.

**4.3.1. Hardware RAID**

RAID, or Redundant Array of Independent Disks, allows a group, or array, of drives to act as a single device. Configure any RAID functions provided by the mainboard of your computer, or attached controller cards, before you begin the installation process. Each active RAID array appears as one drive within Fedora.
On systems with more than one hard drive you may configure Fedora to operate several of the drives as a Linux RAID array without requiring any additional hardware.

### 4.3.2. Software RAID

You can use the Fedora installation program to create Linux software RAID arrays, where RAID functions are controlled by the operating system rather than dedicated hardware. These functions are explained in detail in Section 8.17, "Creating a Custom Layout or Modifying the Default Layout".

### 4.3.3. FireWire and USB Disks

Some FireWire and USB hard disks may not be recognized by the Fedora installation system. If configuration of these disks at installation time is not vital, disconnect them to avoid any confusion.

#### Post-installation Usage

You can connect and configure external FireWire and USB hard disks after installation. Most such devices are recognized by the kernel and available for use at that time.

### 4.4. Do You Have Enough Disk Space?

Nearly every modern-day operating system (OS) uses disk partitions, and Fedora is no exception. When you install Fedora, you may have to work with disk partitions. If you have not worked with disk partitions before (or need a quick review of the basic concepts), refer to Appendix A, An Introduction to Disk Partitions before proceeding.

The disk space used by Fedora must be separate from the disk space used by other OSes you may have installed on your system, such as Windows, OS/2, or even a different version of Linux. For x86, AMD64, and Intel 64 systems, at least two partitions (/ and swap) must be dedicated to Fedora.

Before you start the installation process, you must

- have enough unpartitioned disk space for the installation of Fedora, or
- have one or more partitions that may be deleted, thereby freeing up enough disk space to install Fedora.

To gain a better sense of how much space you really need, refer to the recommended partitioning sizes discussed in Section 8.17.5, “Recommended Partitioning Scheme”.

If you are not sure that you meet these conditions, or if you want to know how to create free disk space for your Fedora installation, refer to Appendix A, An Introduction to Disk Partitions.

### 4.5. Selecting an Installation Method

What type of installation method do you wish to use? The following installation methods are available:

**DVD**

If you have a DVD drive and the Fedora DVD you can use this method. Refer to Section 8.3.1, "Installing from DVD", for DVD installation instructions.

If you booted the installation from a piece of media other than the installation DVD, you can specify the DVD as the installation source with the `linux askmethod` or `linux repo=cdrom:device:/device` boot option, or by selecting Local CD/DVD on the Installation Method menu (refer to Section 8.3, “Installation Method”).
Choose a boot method

CD set
If you have a CD drive and the set of Fedora CDs you can use this method. Refer to Section 8.3.1, “Installing from DVD” for CD installation instructions.

If you booted the installation from a piece of media other than the set of installation CDs, you can specify the CD as the installation source with the `linux askmethod` or `linux repo=cdrom:device:/device` boot option, or by selecting Local CD/DVD on the Installation Method menu (refer to Section 8.3, “Installation Method”).

Live CD
If you have a CD drive and the Fedora live CD you can use this method. The live CD desktop includes an icon labeled Install to Hard Drive. Refer to Section 8.3.1, “Installing from DVD” for CD installation instructions.

Hard Drive
If you have copied the Fedora ISO images to a local hard drive, you can use this method. You need a boot CD-ROM (use the `linux askmethod` or `linux repo=hd:device:/path` boot option), or by selecting Hard drive on the Installation Method menu (refer to Section 8.3, “Installation Method”). Refer to Section 8.3.2, “Installing from a Hard Drive”, for hard drive installation instructions.

NFS
If you are installing from an NFS server using ISO images or a mirror image of Fedora, you can use this method. You need a boot CD-ROM (use the `linux askmethod` or `linux repo=nfs:server:options:/path` boot option, or the NFS directory option on the Installation Method menu described in Section 8.3, “Installation Method”). Refer to Section 8.3.4, “Installing via NFS” for network installation instructions. Note that NFS installations may also be performed in GUI mode.

URL
If you are installing directly from an HTTP (Web) server or FTP server, use this method. You need a boot CD-ROM (use the `linux askmethod` or `linux repo=ftp://user:password@host/path`, or `linux repo=http://host/path` boot option, or the URL option on the Installation Method menu described in Section 8.3, “Installation Method”). Refer to Section 8.3.5, “Installing via FTP or HTTP”, for FTP and HTTP installation instructions.

If you booted the distribution DVD and did not use the alternate installation source option `askmethod`, the next stage loads automatically from the DVD. Proceed to Section 8.6, “Language Selection”.

DVD Activity
If you boot from a Fedora installation DVD, the installation program loads its next stage from that disc. This happens regardless of which installation method you choose, unless you eject the disc before you proceed. The installation program still downloads package data from the source you choose.

4.6. Choose a boot method
You can use several methods to boot Fedora.

Installing from a CD-ROM or DVD requires that you have a Fedora 14 CD-ROM or DVD, and you have a DVD/CD-ROM drive on a system that supports booting from it.
Chapter 4. Planning for Installation on the x86 Architecture

Your BIOS may need to be changed to allow booting from your DVD/CD-ROM drive. For more information about changing your BIOS, refer to Section 7.1.1, “Booting the Installation Program on x86, AMD64, and Intel 64 Systems”.

Other than booting from an installation CD or DVD, you can also boot the Fedora installation program from minimal boot media in the form of a bootable CD or USB flash drive. After you boot the system with a piece of minimal boot media, you complete the installation from a different installation source, such as a local hard drive or a location on a network. Refer to Section 3.3, “Making Minimal Boot Media” for instructions on making boot CDs and USB flash drives.

Finally, you can boot the installer over the network from a preboot execution environment (PXE) server. Refer to Chapter 12, Setting Up an Installation Server. Again, after you boot the system, you complete the installation from a different installation source, such as a local hard drive or a location on a network.
Chapter 5.

Preparing for Installation

5.1. Preparing for a Network Installation

Note

Make sure no installation DVD (or any other type of DVD or CD) is in your system's CD or DVD drive if you are performing a network-based installation. Having a DVD or CD in the drive might cause unexpected errors.

Ensure that you have boot media available on CD, DVD, or a USB storage device such as a flash drive.

The Fedora installation medium must be available for either a network installation (via NFS, FTP, or HTTP) or installation via local storage. Use the following steps if you are performing an NFS, FTP, or HTTP installation.

The NFS, FTP, or HTTP server to be used for installation over the network must be a separate, network-accessible server. It must provide the complete contents of the installation DVD-ROM or the installation CD-ROMs.

Note

The Fedora installation program has the ability to test the integrity of the installation media. It works with the CD, DVD, hard drive ISO, and NFS ISO installation methods. We recommend that you test all installation media before starting the installation process, and before reporting any installation-related bugs (many of the bugs reported are actually due to improperly-burned discs).

To use this test, type the following command at the boot: prompt:

```
linux mediacheck
```

Note

The public directory used to access the installation files over FTP, NFS, or HTTP is mapped to local storage on the network server. For example, the local directory `/var/www/inst/f14` on the network server can be accessed as `http://network.server.com/inst/f14`.

In the following examples, the directory on the installation staging server that will contain the installation files will be specified as `/location/of/disk/space`. The directory that will be made publicly available via FTP, NFS, or HTTP will be specified as `/publicly/available/directory`. For example, `/location/of/disk/space` may be a directory you create called `/var/isos`. `/publicly/available/directory` might be `/var/www/html/f14`, for an HTTP install.

In the following, you will require an ISO image. An ISO image is a file containing an exact copy of the content of a DVD. To create an ISO image from a DVD use the following command:
dd if=/dev/dvd of=/location/of/disk/space/F14.iso

where "dvd" refers to your DVD drive device.

To copy the files from the installation DVD to a Linux instance, which acts as an installation staging server, continue with either Section 5.1.1, "Preparing for FTP and HTTP installation" or Section 5.1.2, "Preparing for an NFS installation".

For details on how to prepare a network installation using a set of CD-ROMs, refer to the instructions in the README-en file on CD-ROM#1.

### 5.1.1. Preparing for FTP and HTTP installation

Extract the files from the ISO image of the installation DVD or set of installation CD-ROMs and place them in a directory that is shared over FTP or HTTP.

Next, make sure that the directory is shared via FTP or HTTP, and verify client access. Test to see whether the directory is accessible from the server itself, and then from another machine on the same subnet to which you will be installing.

### 5.1.2. Preparing for an NFS installation

For NFS installation it is not necessary to extract all the files from the ISO image. It is sufficient to make the ISO image itself, the install.img file, and optionally the product.img file available on the network server via NFS.

1. Transfer the ISO image to the NFS exported directory. On a Linux system, run:

   ```
   mv /location/of/disk/space/F14.iso /publicly/available/directory/
   ```

2. Use a SHA256 checksum program to verify that the ISO image that you copied is intact. Many SHA256 checksum programs are available for various operating systems. On a Linux system, run:

   ```
   $ sha256sum name_of_image.iso
   ```

   where "name_of_image" is the name of the ISO image file. The SHA256 checksum program displays a string of 64 characters called a hash. Compare this hash to the hash displayed for this particular image on the Download Software page on the Red Hat Network (refer to Chapter 2, Obtaining Fedora). The two hashes should be identical.

3. Copy the images/ directory within the ISO file to a directory named images/. Enter the following commands:

   ```
   mount -t iso9660 /path/to/F14.iso /mnt/point -o loop,ro
   cp -pr /mnt/point/images /path/images/
   umount /mnt/point
   ```

4. Verify that the the images/ directory contains at least the install.img file, without which installation cannot proceed. Optionally, the images/ directory should contain the product.img file, without which only the packages for a Minimal installation will be available during the package group selection stage (refer to Section 8.20, "Package Group Selection").
5. Ensure that the `/publicly/available/directory` directory is exported via NFS via an entry in `/etc/exports` on the network server.

To export a directory read-only to a specific system, use:

```
/publicly/available/directory client.ip.address (ro)
```

To export a directory read-only to all systems, use:

```
/publicly/available/directory * (ro)
```

6. On the network server, start the NFS daemon (on a Fedora system, use `/sbin/service nfs start`). If NFS is already running, reload the configuration file (on a Fedora system use `/sbin/service nfs reload`).

7. Be sure to test the NFS share following the directions in the *Fedora Deployment Guide*. Refer to your NFS documentation for details on starting and stopping the NFS server.

**Note**

The Fedora installation program has the ability to test the integrity of the installation media. It works with the CD, DVD, hard drive ISO, and NFS ISO installation methods. We recommend that you test all installation media before starting the installation process, and before reporting any installation-related bugs (many of the bugs reported are actually due to improperly-burned discs). To use this test, type the following command at the boot: prompt:

```
linux mediacheck
```

### 5.2. Preparing for a Hard Drive Installation

**Note — Not all file systems supported**

Hard drive installations only work from ext2, ext3, ext4, or FAT file systems. You cannot use a hard drives formatted for any other file system as an installation source for Fedora.

To check the file system of a hard drive partition on a Windows operating system, use the **Disk Management** tool. To check the file system of a hard drive partition on a Linux operating system, use the **fdisk** tool.

**Cannot Install from LVM Partitions**

You cannot use ISO files on partitions controlled by LVM (Logical Volume Management).
Chapter 5. Preparing for Installation

- an ISO image of the installation DVD. An ISO image is a file that contains an exact copy of the content of a DVD.
- an install.img file extracted from the ISO image.
- optionally, a product.img file extracted from the ISO image.

With these files present on a hard drive, you can choose Hard drive as the installation source when you boot the installation program (refer to Section 8.3, “Installation Method”).

Ensure that you have boot media available on CD, DVD, or a USB storage device such as a flash drive.

To prepare a hard drive as an installation source, follow these steps:

1. Obtain an ISO image of the Fedora installation DVD (refer to Chapter 2, Obtaining Fedora). Alternatively, if you have the DVD on physical media, you can create an image of it with the following command on a Linux system:

   ```sh
dd if=/dev/dvd of=/location/of/disk/space/F14.iso
   ```

   where `dvd` refers to your DVD drive device.

2. Transfer the ISO image to the hard drive.

   The ISO image must be located on a hard drive that is either internal to the computer on which you will install Fedora, or on a hard drive that is attached to that computer by USB.

3. Use a SHA256 checksum program to verify that the ISO image that you copied is intact. Many SHA256 checksum programs are available for various operating systems. On a Linux system, run:

   ```sh
   $ sha256sum name_of_image.iso
   ```

   where `name_of_image` is the name of the ISO image file. The SHA256 checksum program displays a string of 64 characters called a hash. Compare this hash to the hash displayed for this particular image on the Download Software page on the Red Hat Network (refer to Chapter 2, Obtaining Fedora). The two hashes should be identical.

4. Copy the images/ directory within the ISO file to a directory named images/. Enter the following commands:

   ```sh
   mount -t iso9660 /path/to/F14.iso /mnt/point -o loop,ro
   cp -pr /mnt/point/images /path/images/
   umount /mnt/point
   ```

5. Verify that the the images/ directory contains at least the install.img file, without which installation cannot proceed. Optionally, the images/ directory should contain the product.img file, without which only the packages for a Minimal installation will be available during the package group selection stage (refer to Section 8.20, “Package Group Selection”).

System Specifications List

The most recent list of supported hardware can be found at http://hardware.redhat.com/hcl/.

The installation program automatically detects and installs your computer’s hardware. Although you should make sure that your hardware meets the minimum requirements to install Fedora (refer to Section 4.2, “Is Your Hardware Compatible?”) you do not usually need to supply the installation program with any specific details about your system.

However, when performing certain types of installation, some specific details might be useful or even essential.

- If you plan to use a customized partition layout, record:
  - The model numbers, sizes, types, and interfaces of the hard drives attached to the system. For example, Seagate ST3320613AS 320 GB on SATA0, Western Digital WD7500AAKS 750 GB on SATA1. This will allow you to identify specific hard drives during the partitioning process.

- If you are installing Fedora as an additional operating system on an existing system, record:
  - The mount points of the existing partitions on the system. For example, /boot on sda1, / on sda2, and /home on sdb1. This will allow you to identify specific partitions during the partitioning process.

- If you plan to install from an image on a local hard drive:
  - The hard drive and directory that holds the image.

- If you plan to install from a network location, or install on an iSCSI target:
  - The make and model numbers of the network adapters on your system. For example, Netgear GA311. This will allow you to identify adapters when manually configuring the network.
  - IP, DHCP, and BOOTP addresses
  - Netmask
  - Gateway IP address
  - One or more name server IP addresses (DNS)

If any of these networking requirements or terms are unfamiliar to you, contact your network administrator for assistance.

- If you plan to install from a network location:
  - The location of the image on an FTP server, HTTP (web) server, or NFS server – see Section 8.3.5, “Installing via FTP or HTTP” and Section 8.3.4, “Installing via NFS” for examples.

- If you plan to install on an iSCSI target:
  - The location of the iSCSI target. Depending on your network, you might also need a CHAP username and password, and perhaps a reverse CHAP username and password – see Section 8.8.1.1, “Advanced Storage Options”.

- If your computer is part of a domain:
Chapter 6. System Specifications List

- You should verify that the domain name will be supplied by the DHCP server. If not, you will need to input the domain name manually during installation.
Chapter 7.

Booting the Installer

**Important — UEFI for 32-bit x86 systems**

Fedora 14 does not support UEFI for 32-bit x86 systems.

**Important — UEFI for AMD64 and Intel 64**

Note that the boot configurations of UEFI and BIOS differ significantly from each other. Therefore, the installed system must boot using the same firmware that was used during installation. You cannot install the operating system on a system that uses BIOS and then boot this installation on a system that uses UEFI.

Fedora 14 supports version 2.2 of the UEFI specification. Hardware that supports version 2.3 of the UEFI specification or later should boot and operate with Fedora 14, but the additional functionality defined by these later specifications will not be available. The UEFI specifications are available from [http://www.uefi.org/specs/agreement/](http://www.uefi.org/specs/agreement/)

To start the installation program from a Fedora DVD or from minimal boot media, follow this procedure:

1. Disconnect any external FireWire or USB disks that you do not need for installation. Refer to Section 4.3.3, "FireWire and USB Disks" for more information.

2. Power on your computer system.

3. Insert the media in your computer.

4. Power off your computer with the boot media still inside.

5. Power on your computer system.

You might need to press a specific key or combination of keys to boot from the media. On most computers, a message appears briefly on the screen very soon after you turn on the computer. Typically, it is worded something like **Press F10 to select boot device**, although the specific wording and the key that you must press varies widely from computer to computer. Consult the documentation for your computer or motherboard, or seek support from the hardware manufacturer or vendor. On Apple computers, the **C** key boots the system from the DVD drive. On older Apple hardware you might need to press **Cmd+Opt+Shift+Del** to boot from the DVD drive.

If your computer does not allow you to select a boot device as it starts up, you might need to configure your system's **Basic Input/Output System** (BIOS) to boot from the media.

To change your BIOS settings on an x86, AMD64, or Intel 64 system, watch the instructions provided on your display when your computer first boots. A line of text appears, telling you which key to press to enter the BIOS settings.

Once you have entered your BIOS setup program, find the section where you can alter your boot sequence. The default is often C, A or A, C (depending on whether you boot from your hard drive [C] or a diskette drive [A]). Change this sequence so that the DVD is first in your boot order and that C or A (whichever is your typical boot default) is second. This instructs the computer to first look at the DVD drive for bootable media; if it does not find bootable media on the DVD drive, it then checks your hard drive or diskette drive.
Chapter 7. Booting the Installer

Save your changes before exiting the BIOS. For more information, refer to the documentation that came with your system.

Note — Aborting the Installation

To abort the installation, either press Ctrl + Alt + Del or power off your computer with the power switch. You may abort the installation process without consequence at any time prior to selecting Write changes to disk on the Write partitioning to disk screen. Fedora makes no permanent changes to your computer until that point. Please be aware that stopping the installation after partitioning has begun can leave your computer unusable.

7.1. Starting the Installation Program

Important — UEFI for 32-bit x86 systems

Fedora 14 does not support UEFI for 32-bit x86 systems.

Important — UEFI for AMD64 and Intel 64

Note that the boot configurations of UEFI and BIOS differ significantly from each other. Therefore, the installed system must boot using the same firmware that was used during installation. You cannot install the operating system on a system that uses BIOS and then boot this installation on a system that uses UEFI.

Fedora 14 supports version 2.2 of the UEFI specification. Hardware that supports version 2.3 of the UEFI specification or later should boot and operate with Fedora 14, but the additional functionality defined by these later specifications will not be available. The UEFI specifications are available from http://www.uefi.org/specs/agreement/

To start, first make sure that you have all necessary resources for the installation. If you have already read through Chapter 4, Planning for Installation on the x86 Architecture, and followed the instructions, you should be ready to start the installation process. When you have verified that you are ready to begin, boot the installation program using the Fedora DVD or CD-ROM#1 or any boot media that you have created.

7.1.1. Booting the Installation Program on x86, AMD64, and Intel 64 Systems

You can boot the installation program using any one of the following media (depending upon what your system can support):

- **Fedora DVD** — Your machine supports a bootable DVD drive and you have the Fedora installation DVD.
- **Set of Fedora CDs** — Your machine supports a bootable CD drive and you have a set of Fedora installation CDs.
- **Fedora live CD** — Your machine supports a bootable CD drive and you have a Fedora live CD.
Booting the Installation Program on x86, AMD64, and Intel 64 Systems

- **Boot CD-ROM** — Your machine supports a bootable CD-ROM drive and you want to perform network or hard drive installation.

- **USB flash drive** — Your machine supports booting from a USB device.

- **PXE boot via network** — Your machine supports booting from the network. This is an advanced installation path. Refer to Chapter 12, Setting Up an Installation Server for additional information on this method.

To create a boot CD-ROM or to prepare your USB flash drive for booting or installation, refer to Section 3.3, “Making Minimal Boot Media”.

Insert the boot media and reboot the system.

You might need to press a specific key or combination of keys to boot from the media. On most computers, a message appears briefly on the screen very soon after you turn on the computer. Typically, it is worded something like **Press F10 to select boot device**, although the specific wording and the key that you must press varies widely from computer to computer. Consult the documentation for your computer or motherboard, or seek support from the hardware manufacturer or vendor. On Apple computers, the C key boots the system from the DVD drive. On older Apple hardware you might need to press **Cmd+Opt+Shift+Del** to boot from the DVD drive.

If your computer does not allow you to select a boot device as it starts up, you might need to configure your system’s Basic Input/Output System (BIOS) to boot from the media.

To change your BIOS settings on an x86, AMD64, or Intel 64 system, watch the instructions provided on your display when your computer first boots. A line of text appears, telling you which key to press to enter the BIOS settings.

Once you have entered your BIOS setup program, find the section where you can alter your boot sequence. The default is often C, A or A, C (depending on whether you boot from your hard drive [C] or a diskette drive [A]). Change this sequence so that the DVD is first in your boot order and that C or A (whichever is your typical boot default) is second. This instructs the computer to first look at the DVD drive for bootable media; if it does not find bootable media on the DVD drive, it then checks your hard drive or diskette drive.

Save your changes before exiting the BIOS. For more information, refer to the documentation that came with your system.

After a short delay, a screen containing the **boot:** prompt should appear. The screen contains information on a variety of boot options. Each boot option also has one or more help screens associated with it. To access a help screen, press the appropriate function key as listed in the line at the bottom of the screen.

As you boot the installation program, be aware of two issues:

- Once the **boot:** prompt appears, the installation program automatically begins if you take no action within the first minute. To disable this feature, press one of the help screen function keys.

- If you press a help screen function key, there is a slight delay while the help screen is read from the boot media.

Normally, you only need to press **Enter** to boot. Be sure to watch the boot messages to review if the Linux kernel detects your hardware. If your hardware is properly detected, continue to the next section. If it does not properly detect your hardware, you may need to restart the installation and use one of the boot options provided in Chapter 10, Boot Options.
Chapter 7. Booting the Installer

7.1.2. Additional Boot Options

While it is easiest to boot using a DVD and perform a graphical installation, sometimes there are installation scenarios where booting in a different manner may be needed. This section discusses additional boot options available for Fedora.

To pass options to the boot loader on an x86, AMD64, or Intel 64 system, use the instructions as provided in the boot loader option samples below.

**Note**

Refer to *Chapter 10, Boot Options* for additional boot options not covered in this section.

• To perform a text mode installation, at the installation boot prompt, type:

```plaintext
linux text
```

• To specify an installation source, use the `linux repo=` option. For example:

```plaintext
linux repo=cdrom:device

linux repo=ftp://username:password@URL

linux repo=http://URL

linux repo=hd:device

linux repo=nfs:options:server:/path

linux repo=nfsiso:options:server:/path
```

In these examples, `cdrom` refers to a CD or DVD drive, `ftp` refers to a location accessible by FTP, `http` refers to a location accessible by HTTP, `hd` refers to an ISO image file accessible on a hard drive partition, `nfs` refers to an expanded tree of installation files accessible by NFS, and `nfsiso` refers to an ISO image file accessible by NFS.

• ISO images have an SHA256 checksum embedded in them. To test the checksum integrity of an ISO image, at the installation boot prompt, type:

```plaintext
linux mediacheck
```

The installation program prompts you to insert a disc or select an ISO image to test, and click OK to perform the checksum operation. This checksum operation can be performed on any Fedora disc
and does not have to be performed in a specific order (for example, CD #1 does not have to be the first CD you verify). It is strongly recommended to perform this operation on any Fedora CD or DVD that was created from downloaded ISO images. This command works with the CD, DVD, hard drive ISO, and NFS ISO installation methods.

• If you need to perform the installation in *serial mode*, type the following command:

```
linux console=<device>
```

For text mode installations, use:

```
linux text console=<device>
```

In the above command, `<device>` should be the device you are using (such as ttyS0 or ttyS1). For example, `linux text console=ttyS0`.

Text mode installations using a serial terminal work best when the terminal supports UTF-8. Under UNIX and Linux, Kermit supports UTF-8. For Windows, Kermit '95 works well. Non-UTF-8 capable terminals works as long as only English is used during the installation process. An enhanced serial display can be used by passing the `utf8` command as a boot-time option to the installation program. For example:

```
linux console=ttyS0 utf8
```

### 7.1.2.1. Kernel Options

Options can also be passed to the kernel. For example, to apply updates for the anaconda installation program from a USB storage device enter:

```
linux updates
```

For text mode installations, use:

```
linux text updates
```

This command results in a prompt for the path to the device that contains updates for *anaconda*. It is not needed if you are performing a network installation and have already placed the updates image contents in `rhupdates/` on the server.

After entering any options, press **Enter** to boot using those options.

If you need to specify boot options to identify your hardware, please write them down. The boot options are needed during the boot loader configuration portion of the installation (refer to Section 8.19, "x86, AMD64, and Intel 64 Boot Loader Configuration" for more information).

For more information on kernel options refer to *Chapter 10, Boot Options*. 
7.2. The Boot Menu

The boot media displays a graphical boot menu with several options. If no key is hit within 60 seconds, the default boot option runs. To choose the default, either wait for the timer to run out or hit Enter on the keyboard. To select a different option than the default, use the arrow keys on your keyboard, and hit Enter when the correct option is highlighted. If you want to customize the boot options for a particular option, press the Tab key.

![Figure 7.1. The boot screen](image)

For a listing and explanation of common boot options, refer to Chapter 10, Boot Options.

The boot menu options are:

Install or upgrade an existing system
This option is the default. Choose this option to install Fedora onto your computer system using the graphical installation program.

Install system with basic video driver
This option allows you to install Fedora in graphical mode even if the installation program is unable to load the correct driver for your video card. If your screen appears distorted or goes blank when using the Install or upgrade an existing system option, restart your computer and try this option instead.

Rescue installed system
Choose this option to repair a problem with your installed Fedora system that prevents you from booting normally. Although Fedora is an exceptionally stable computing platform, it is still possible for occasional problems to occur that prevent booting. The rescue environment contains utility programs that allow you to fix a wide variety of these problems.
7.3. Installing from a Different Source

You can install Fedora from the ISO images stored on hard disk, or from a network using NFS, FTP, or HTTP methods. Experienced users frequently use one of these methods because it is often faster to read data from a hard disk or network server than from a DVD.

The following table summarizes the different boot methods and recommended installation methods to use with each:

<table>
<thead>
<tr>
<th>Boot method</th>
<th>Installation source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installation DVD</td>
<td>DVD, CD set, network, or hard disk</td>
</tr>
<tr>
<td>Set of installation CDs</td>
<td>DVD, CD set, network, or hard disk</td>
</tr>
<tr>
<td>Live CD</td>
<td>Live CD</td>
</tr>
<tr>
<td>Installation USB flash drive</td>
<td>USB flash drive, installation DVD, set of installation CDs, network, or hard disk</td>
</tr>
<tr>
<td>Minimal boot CD or USB, rescue CD</td>
<td>Network or hard disk</td>
</tr>
</tbody>
</table>

Refer to Section 4.5, “Selecting an Installation Method” for information about installing from locations other than the media with which you booted the system.

7.4. Booting from the Network using PXE

To boot with

PXE, you need a properly configured server, and a network interface in your computer that supports PXE. For information on how to configure a PXE server, refer to Chapter 12, Setting Up an Installation Server.

Configure the computer to boot from the network interface. This option is in the BIOS, and may be labeled Network Boot or Boot Services. Once you properly configure PXE booting, the computer can boot the Fedora installation system without any other media.

To boot a computer from a PXE server:

1. Ensure that the network cable is attached. The link indicator light on the network socket should be lit, even if the computer is not switched on.
2. Switch on the computer.
3. A menu screen appears. Press the number key that corresponds to the desired option.

If your PC does not boot from the netboot server, ensure that the BIOS is configured to boot first from the correct network interface. Some BIOS systems specify the network interface as a possible boot device, but do not support the PXE standard. Refer to your hardware documentation for more information.
Note — Multiple NICs and PXE installation

Some servers with multiple network interfaces might not assign eth0 to the first network interface as the firmware interface knows it, which can cause the installer to try to use a different network interface from the one that was used by PXE. To change this behavior, use the following in `pxelinux.cfg/*` config files:

```
IPAPPEND 2
APPEND ksdevice=bootif
```

These configuration options above cause the installer to use the same network interface the firmware interface and PXE use. You can also use the following option:

```
ksdevice=link
```

This option causes the installer to use the first network device it finds that is linked to a network switch.
Installing using anaconda

This chapter describes an installation using the graphical user interface of anaconda.

8.1. The Text Mode Installation Program User Interface

Important — Graphical installation recommended

We recommend that you install Fedora using the graphical interface. If you are installing Fedora on a system that lacks a graphical display, consider performing the installation over a VNC connection – see Chapter 13, Installing Through VNC. If anaconda detects that you are installing in text mode on a system where installation over a VNC connection might be possible, anaconda asks you to verify your decision to install in text mode even though your options during installation are limited.

If your system has a graphical display, but graphical installation fails, try booting with the xdriver=vesa option – refer to Chapter 10, Boot Options.

Note

Not every language supported in graphical installation mode is also supported in text mode. Specifically, languages written with a character set other than the Latin or Cyrillic alphabets are not available in text mode. If you choose a language written with a character set that is not supported in text mode, the installation program will present you with the English versions of the screens.

Important — Graphical Interface on the Installed System

Installing in text mode does not prevent you from using a graphical interface on your system once it is installed.

Apart from the graphical installer, anaconda also includes a text-based installer that includes most of the on-screen widgets commonly found on graphical user interfaces. Figure 8.1, “Installation Program Widgets as seen in URL Setup” and Figure 8.2, “Installation Program Widgets as seen in Choose a Language” illustrate widgets that appear on screens during the installation process.
Chapter 8. Installing using anaconda

Figure 8.1. Installation Program Widgets as seen in URL Setup

Figure 8.2. Installation Program Widgets as seen in Choose a Language

If one of the following situations occurs, the installation program uses text mode:

- The installation system fails to identify the display hardware on your computer
- You choose the text mode installation from the boot menu

While text mode installations are not explicitly documented, those using the text mode installation program can easily follow the GUI installation instructions. However, because text mode presents you with a simpler, more streamlined installation process, certain options that are available in graphical mode are not also available in text mode. These differences are noted in the description of the installation process in this guide, and include:
• configuring advanced storage methods such as LVM, RAID, FCoE, zFCP, and iSCSI.
• customizing the partition layout
• customizing the bootloader layout
• selecting packages during installation
• configuring the installed system with Firstboot

If you choose to install Fedora in text mode, you can still configure your system to use a graphical interface after installation. Refer to Section 17.3, “Switching to a Graphical Login” for instructions.

The widgets include:

• Window — Windows (usually referred to as dialogs in this manual) appear on your screen throughout the installation process. At times, one window may overlay another; in these cases, you can only interact with the window on top. When you are finished in that window, it disappears, allowing you to continue working in the window underneath.

• Checkbox — Checkboxes allow you to select or deselect a feature. The box displays either an asterisk (selected) or a space (unselected). When the cursor is within a checkbox, press Space to select or deselect a feature.

• Text Input — Text input lines are regions where you can enter information required by the installation program. When the cursor rests on a text input line, you may enter and/or edit information on that line.

• Text Widget — Text widgets are regions of the screen for the display of text. At times, text widgets may also contain other widgets, such as checkboxes. If a text widget contains more information than can be displayed in the space reserved for it, a scroll bar appears; if you position the cursor within the text widget, you can then use the Up and Down arrow keys to scroll through all the information available. Your current position is shown on the scroll bar by a # character, which moves up and down the scroll bar as you scroll.

• Scroll Bar — Scroll bars appear on the side or bottom of a window to control which part of a list or document is currently in the window's frame. The scroll bar makes it easy to move to any part of a file.

• Button Widget — Button widgets are the primary method of interacting with the installation program. You progress through the windows of the installation program by navigating these buttons, using the Tab and Enter keys. Buttons can be selected when they are highlighted.

• Cursor — Although not a widget, the cursor is used to select (and interact with) a particular widget. As the cursor is moved from widget to widget, it may cause the widget to change color, or the cursor itself may only appear positioned in or next to the widget. In Figure 8.1, “Installation Program Widgets as seen in URL Setup”, the cursor is positioned on the OK button. Figure 8.2, “Installation Program Widgets as seen in Choose a Language”, shows the cursor on the Edit button.

8.1.1. Using the Keyboard to Navigate

Navigation through the installation dialogs is performed through a simple set of keystrokes. To move the cursor, use the Left, Right, Up, and Down arrow keys. Use Tab, and Shift-Tab to cycle forward or backward through each widget on the screen. Along the bottom, most screens display a summary of available cursor positioning keys.
To "press" a button, position the cursor over the button (using Tab, for example) and press Space or Enter. To select an item from a list of items, move the cursor to the item you wish to select and press Enter. To select an item with a checkbox, move the cursor to the checkbox and press Space to select an item. To deselect, press Space a second time.

Pressing F12 accepts the current values and proceeds to the next dialog; it is equivalent to pressing the OK button.

**Warning**

Unless a dialog box is waiting for your input, do not press any keys during the installation process (doing so may result in unpredictable behavior).

### 8.2. The Graphical Installation Program User Interface

If you have used a graphical user interface (GUI) before, you are already familiar with this process; use your mouse to navigate the screens, click buttons, or enter text fields.

You can also navigate through the installation using the keyboard. The Tab key allows you to move around the screen, the Up and Down arrow keys to scroll through lists, + and - keys expand and collapse lists, while Space and Enter selects or removes from selection a highlighted item. You can also use the Alt+X key command combination as a way of clicking on buttons or making other screen selections, where X is replaced with any underlined letter appearing within that screen.

**Note**

If you do not wish to use the GUI installation program, the text mode installation program is also available. To start the text mode installation program, use the following command at the boot:

```
prompt: linux text
```

Refer to Section 7.2, “The Boot Menu” for a description of the Fedora boot menu and to Chapter 8, Installing using anaconda for a brief overview of text mode installation instructions.

It is highly recommended that installs be performed using the GUI installation program. The GUI installation program offers the full functionality of the Fedora installation program, including LVM configuration which is not available during a text mode installation.

Users who must use the text mode installation program can follow the GUI installation instructions and obtain all needed information.

### 8.2.1. Screenshots during installation

Anaconda allows you to take screenshots during the installation process. At any time during installation, press Shift+Print Screen and anaconda will save a screenshot to /root/anaconda-screenshots.

If you are performing a Kickstart installation, use the autostep --autoscreenshot option to generate a screenshot of each step of the installation automatically. Refer to Section 14.3, “Creating the Kickstart File” for details of configuring a Kickstart file.
8.2.2. A Note about Virtual Consoles

The Fedora installation program offers more than the dialog boxes of the installation process. Several kinds of diagnostic messages are available to you, as well as a way to enter commands from a shell prompt. The installation program displays these messages on five virtual consoles, among which you can switch using a single keystroke combination.

A virtual console is a shell prompt in a non-graphical environment, accessed from the physical machine, not remotely. Multiple virtual consoles can be accessed simultaneously.

These virtual consoles can be helpful if you encounter a problem while installing Fedora. Messages displayed on the installation or system consoles can help pinpoint a problem. Refer to Table 8.1, "Console, Keystrokes, and Contents" for a listing of the virtual consoles, keystrokes used to switch to them, and their contents.

Generally, there is no reason to leave the default console (virtual console #6) for graphical installations unless you are attempting to diagnose installation problems.

Table 8.1. Console, Keystrokes, and Contents

<table>
<thead>
<tr>
<th>console</th>
<th>keystrokes</th>

</tr>
</tbody>
</table>

8.3. Installation Method

If you booted the installation from minimal boot media or with the askmethod boot option, use the arrow keys on your keyboard to select an installation method (refer to Figure 8.3, "Installation Method"). With your selected method highlighted, press the Tab key to move to the OK button and press the Enter key to confirm your choice.
8.3.1. Installing from DVD

To install Fedora from a DVD, place the DVD in your DVD drive and boot your system from the DVD. Even if you booted from alternative media, you can still install Fedora from DVD media.

The installation program then probes your system and attempts to identify your DVD drive. It starts by looking for an IDE (also known as an ATAPI) DVD drive.

![Note]

To abort the installation process at this time, reboot your machine and then eject the boot media. You can safely cancel the installation at any point before the **Write changes to disk** screen. Refer to Section 8.18, "Write changes to disk" for more information.

If your DVD drive is not detected, and it is a SCSI DVD, the installation program prompts you to choose a SCSI driver. Choose the driver that most closely resembles your adapter. You may specify options for the driver if necessary; however, most drivers detect your SCSI adapter automatically.

If the DVD drive is found and the driver loaded, the installer will present you with the option to perform a media check on the DVD. This will take some time, and you may opt to skip over this step. However, if you later encounter problems with the installer, you should reboot and perform the media check before calling for support. From the media check dialog, continue to the next stage of the installation process (refer to Section 8.5, "Welcome to Fedora").

8.3.2. Installing from a Hard Drive

The **Select Partition** screen applies only if you are installing from a disk partition (that is, you selected **Hard Drive** in the **Installation Method** dialog). This dialog allows you to name the disk partition and directory from which you are installing Fedora. If you used the `repo=hd` boot option, you already specified a partition.

![Figure 8.4. Selecting Partition Dialog for Hard Drive Installation]
Select the partition containing the ISO files from the list of available partitions. Internal IDE, SATA, SCSI, and USB drive device names begin with `/dev/sd`. Each individual drive has its own letter, for example `/dev/sda`. Each partition on a drive is numbered, for example `/dev/sda1`.

Also specify the **Directory holding images**. Enter the full directory path from the drive that contains the ISO image files. The following table shows some examples of how to enter this information:

**Table 8.2. Location of ISO images for different partition types**

<table>
<thead>
<tr>
<th>Partition type</th>
<th>Volume</th>
<th>Original path to files</th>
<th>Directory to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>VFAT</td>
<td>D:\</td>
<td>D:\Downloads\F14</td>
<td>/Downloads/F14</td>
</tr>
<tr>
<td>ext2, ext3, ext4</td>
<td>/home</td>
<td>/home/user1/F14</td>
<td>/user1/F14</td>
</tr>
</tbody>
</table>

If the ISO images are in the root (top-level) directory of a partition, enter a `/`. If the ISO images are located in a subdirectory of a mounted partition, enter the name of the directory holding the ISO images within that partition. For example, if the partition on which the ISO images is normally mounted as `/home/`, and the images are in `/home/new/`, you would enter `/new/`.

**Use a leading slash**

An entry without a leading slash may cause the installation to fail.

Select **OK** to continue. Proceed with *Chapter 8, Installing using anaconda*.

### 8.3.3. Performing a Network Installation

The installation program is network-aware and can use network settings for a number of functions. For instance, if you boot the installer with the `askmethod` or `repo=` options, you can install Fedora from a network server using FTP, HTTP, or NFS protocols. You can also instruct the installation program to consult additional software repositories later in the process.

If you are performing a network installation, the **Configure TCP/IP** dialog appears. This dialog asks for your IP and other network addresses. You can choose to configure the IP address and Netmask of the device via DHCP or manually.

By default, the installation program uses DHCP to automatically provide network settings. If you use a cable or DSL modem, router, firewall, or other network hardware to communicate with the Internet, DHCP is a suitable option. If your network has no DHCP server, clear the check box labeled **Use dynamic IP configuration (DHCP)**.

Enter the IP address you are using during installation and press **Enter**.

The installation program supports the IPv4 and IPv6 protocols.
Chapter 8. Installing using anaconda

48

Figure 8.5. TCP/IP Configuration

When the installation process completes, it will transfer these settings to your system.

- If you are installing via NFS, proceed to Section 8.3.4, “Installing via NFS”.
- If you are installing via Web or FTP, proceed to Section 8.3.5, “Installing via FTP or HTTP”.

8.3.4. Installing via NFS

The NFS dialog applies only if you selected NFS Image in the Installation Method dialog. If you used the repo=nfs boot option, you already specified a server and path.

Enter the domain name or IP address of your NFS server. For example, if you are installing from a host named eastcoast in the domain example.com, enter eastcoast.example.com in the NFS Server field.

Next, enter the name of the exported directory. If you followed the setup described in Section 5.1.2, “Preparing for an NFS installation”, you would enter the directory /export/directory/.

This dialog also allows you to specify NFS mount options. Refer to the Fedora Deployment Guide for a list of common NFS mount options, or consult the man pages for mount and nfs for a comprehensive list of options.

If the NFS server is exporting a mirror of the Fedora installation tree, enter the directory which contains the root of the installation tree. You will enter an Installation Key later on in the process which will determine which subdirectories are used to install from. If everything was specified properly, a message appears indicating that the installation program for Fedora is running.
If the NFS server is exporting the ISO image of the Fedora DVD, enter the directory which contains the ISO image.

Proceed with Chapter 8, Installing using anaconda.

### 8.3.5. Installing via FTP or HTTP

**Important — you must specify the protocol**

When you provide a URL to an installation source, you must explicitly specify http:// or ftp:// as the protocol.

The URL dialog applies only if you are installing from a FTP or HTTP server (if you selected URL in the Installation Method dialog). This dialog prompts you for information about the FTP or HTTP server from which you are installing Fedora. If you used the repo=ftp or repo=http boot option, you already specified a server and path.

Enter the name or IP address of the FTP or HTTP site from which you are installing, and the name of the directory that contains the /images directory for your architecture. For example:

/pub/fedora/linux/releases/14/Fedora/i386/os/

Specify the address of a proxy server, and if necessary, provide a port number, username, and password. If everything was specified properly, a message box appears indicating that files are being retrieved from the server.

If your FTP or HTTP server requires user authentication, specify user and password as part of the URL as follows:

```
{ftp|http}://<user>:<password>@<hostname>[:<port>]/<directory>/
```

For example:

```
http://install:f14pw@name.example.com/pub/fedora/linux/releases/14/Fedora/i386/os/
```
8.4. Verifying Media

The DVD offers an option to verify the integrity of the media. Recording errors sometimes occur while producing DVD media. An error in the data for package chosen in the installation program can cause the installation to abort. To minimize the chances of data errors affecting the installation, verify the media before installing.

If the verification succeeds, the installation process proceeds normally. If the process fails, create a new DVD using the ISO image you downloaded earlier.

8.5. Welcome to Fedora

The Welcome screen does not prompt you for any input.
Click on the Next button to continue.

8.6. Language Selection

Using your mouse, select a language to use for the installation (refer to Figure 8.8, “Language Selection”).

The language you select here will become the default language for the operating system once it is installed. Selecting the appropriate language also helps target your time zone configuration later in the installation. The installation program tries to define the appropriate time zone based on what you specify on this screen.

To add support for additional languages, customize the installation at the package selection stage. For more information, refer to Section 8.20.2, “Customizing the Software Selection”.
Figure 8.8. Language Selection

Once you select the appropriate language, click **Next** to continue.

### 8.7. Keyboard Configuration

Using your mouse, select the correct layout type (for example, U.S. English) for the keyboard you would prefer to use for the installation and as the system default (refer to the figure below).

Once you have made your selection, click **Next** to continue.

Figure 8.9. Keyboard Configuration
Fedora includes support for more than one keyboard layout for many languages. In particular, most European languages include a latin1 option, which uses dead keys to access certain characters, such as those with diacritical marks. When you press a dead key, nothing will appear on your screen until you press another key to “complete” the character. For example, to type é on a latin1 keyboard layout, you would press (and release) the ' key, and then press the E key. By contrast, you access this character on some other keyboards by pressing and holding down a key (such as Alt-Gr) while you press the E key. Other keyboards might have a dedicated key for this character.

**Note**

To change your keyboard layout type after you have completed the installation, use the Keyboard Configuration Tool.

Type the `system-config-keyboard` command in a shell prompt to launch the Keyboard Configuration Tool. If you are not root, it prompts you for the root password to continue.

### 8.8. Storage Devices

You can install Fedora on a large variety of storage devices. This screen allows you to select either basic or specialized storage devices.

**What type of devices will your installation involve?**

- **Basic Storage Devices**
  - Installs or upgrades to typical types of storage devices. If you’re not sure which option is right for you, this is probably it.

- **Specialized Storage Devices**
  - Installs or upgrades to devices such as Storage Area Networks (SANs) or mainframe attached disks (DASE), usually in an enterprise environment.

**Figure 8.10. Storage devices**

**Basic Storage Devices**

Select **Basic Storage Devices** to install Fedora on the following storage devices:

- hard drives or solid-state drives connected directly to the local system.

**Specialized Storage Devices**

Select **Specialized Storage Devices** to install Fedora on the following storage devices:

- Storage area networks (SANs)
Chapter 8. Installing using anaconda

- Direct access storage devices (DASDs)
- Firmware RAID devices
- Multipath devices

Use the Specialized Storage Devices option to configure Internet Small Computer System Interface (iSCSI) and FCoE (Fiber Channel over Ethernet) connections.

If you select Basic Storage Devices, anaconda automatically detects the local storage attached to the system and does not require further input from you. Proceed to Section 8.9, “Setting the Hostname”.

8.8.1. The Storage Devices Selection Screen

The storage devices selection screen displays all storage devices to which anaconda has access.

![Storage Devices Selection Screen](image)

Figure 8.11. Select storage devices — Basic devices
The Storage Devices Selection Screen

Figure 8.12. Select storage devices — Multipath Devices

Please select the drives you'd like to install the operating system on, as well as any drives you'd like to automatically mount to your system, below:

![Screen shot of storage devices selection screen]

0 device(s) (0 MB) selected out of 4 device(s) (21078 MB) total.

**Tip:** Selecting a drive on this screen does not necessarily mean it will be wiped by the installation process. Also, note that post-installation you may mount drives you did not select here by modifying your /etc/fstab file.

Figure 8.13. Select storage devices — Other SAN Devices

Please select the drives you'd like to install the operating system on, as well as any drives you'd like to automatically mount to your system, below:

![Screen shot of storage devices selection screen]

0 device(s) (0 MB) selected out of 11 device(s) (43352 MB) total.

**Tip:** Selecting a drive on this screen does not necessarily mean it will be wiped by the installation process. Also, note that post-installation you may mount drives you did not select here by modifying your /etc/fstab file.

Devices are grouped under the following tabs:

**Basic Devices**

Basic storage devices directly connected to the local system, such as hard disk drives and solid-state drives.
Chapter 8. Installing using anaconda

Firmware RAID
   Storage devices attached to a firmware RAID controller.

Multipath Devices
   Storage devices accessible through more than one path, such as through multiple SCSI
   controllers or Fiber Channel ports on the same system.

Other SAN Devices
   Any other devices available on a storage area network (SAN).

If you do need to configure iSCSI or FCoE storage, click **Add Advanced Target** and refer to
Section 8.8.1.1, “Advanced Storage Options”.

The storage devices selection screen also contains a **Search** tab that allows you to filter storage
devices either by their **World Wide Identifier (WWID)** or by the port, target, or **logical unit number**
(LUN) at which they are accessed.

![Figure 8.14. The Storage Devices Search Tab](image)

The tab contains a drop-down menu to select searching by port, target, WWID, or LUN (with
corresponding text boxes for these values). Searching by WWID or LUN requires additional values in
the corresponding text box.

Each tab presents a list of devices detected by **anaconda**, with information about the device to
help you to identify it. A small drop-down menu marked with an icon is located to the right of the
column headings. This menu allows you to select the types of data presented on each device. For
example, the menu on the **Multipath Devices** tab allows you to specify any of **WWID, Capacity,**
**Vendor, Interconnect**, and **Paths** to include among the details presented for each device. Reducing
or expanding the amount of information presented might help you to identify particular devices.

![Figure 8.15. Selecting Columns](image)

Each device is presented on a separate row, with a checkbox to its left. Click the checkbox to make
device available during the installation process, or click the **radio button** at the left of the column
headings to select or deselect all the devices listed in a particular screen. Later in the installation
process, you can choose to install Fedora onto any of the devices selected here, and can choose to
automatically mount any of the other devices selected here as part of the installed system.

Note that the devices that you select here are not automatically erased by the installation process.
Selecting a device on this screen does not, in itself, place data stored on the device at risk. Note also
that any devices that you do not select here to form part of the installed system can be added to the
system after installation by modifying the `/etc/fstab` file.
Important — chain loading

Any storage devices that you do not select on this screen are hidden from anaconda entirely. To chain load the Fedora boot loader from a different boot loader, select all the devices presented in this screen.

when you have selected the storage devices to make available during installation, click Next and proceed to Section 8.13, “Initializing the Hard Disk”

8.8.1.1. Advanced Storage Options

From this screen you can configure an iSCSI (SCSI over TCP/IP) target or FCoE (Fibre channel over ethernet) SAN (storage area network). Refer to Appendix B, ISCSI disks for an introduction to iSCSI.

Figure 8.16. Advanced Storage Options

8.8.1.1.1. Enable Network Interfaces

Use this dialog to configure the network interfaces through which the system will connect to networked storage devices.
Chapter 8. Installing using anaconda

Figure 8.17. Enable Network Interface

If your network does not have DHCP enabled, or if you need to override the DHCP settings, select the network interface that you plan to use from the Interfaces menu. Clear the checkbox for Use dynamic IP configuration (DHCP). You can now enter an IPv4 address and netmask for this system in the form address / netmask, along with the gateway address and nameserver address for your network.

Click OK to accept these settings and continue.

8.8.1.1.2. Configure iSCSI Parameters

To configure an iSCSI target invoke the 'Configure iSCSI Parameters' dialog by selecting 'Add iSCSI target' and clicking on the 'Add Drive' button. Fill in the details for the iSCSI target IP and provide a unique iSCSI initiator name to identify this system. If the iSCSI target uses CHAP (Challenge Handshake Authentication Protocol) for authentication, enter the CHAP username and password. If your environment uses 2-way CHAP (also called "Mutual CHAP"), also enter the reverse CHAP username and password. Click the 'Add target' button to attempt connection to the iSCSI target using this information.
8.8.1.3. Configure FCoE Parameters

To configure an FCoE SAN, select Add FCoE SAN and click Add Drive.

On the menu that appears in the next dialog box, select the network interface that is connected to your FCoE switch and click Add FCoE Disk(s).

**Configure FCoE Parameters**

Please select the network interface which is connected to your FCoE switch.

NIC: eth0 - ['Advanced', 'Micro', 'Devices', '[AMD]'] ['79c970', 'PCnet32']
- 08:00:27:5E:1B:27

☑️ Use DCB

---

*Data Center Bridging* (DCB) is a set of enhancements to the Ethernet protocols designed to increase the efficiency of Ethernet connections in storage networks and clusters. Enable or disable the installer's awareness of DCB with the checkbox in this dialog.
8.9. Setting the Hostname

Setup prompts you to supply a host name for this computer, either as a fully-qualified domain name (FQDN) in the format \texttt{hostname.doma1name} or as a short host name in the format \texttt{hostname}. Many networks have a Dynamic Host Configuration Protocol (DHCP) service that automatically supplies connected systems with a domain name. To allow the DHCP service to assign the domain name to this machine, specify the short host name only.

Valid Hostnames

You may give your system any name provided that the full hostname is unique. The hostname may include letters, numbers and hyphens.

If your Fedora system is connected directly to the Internet, you must pay attention to additional considerations to avoid service interruptions or risk action by your upstream service provider. A full discussion of these issues is beyond the scope of this document.

Modem Configuration

The installation program does not configure modems. Configure these devices after installation with the \texttt{Network} utility. The settings for your modem are specific to your particular Internet Service Provider (ISP).
8.9.1. Edit Network Connections

Note

To change your network configuration after you have completed the installation, use the Network Administration Tool.

Type the `system-config-network` command in a shell prompt to launch the Network Administration Tool. If you are not root, it prompts you for the root password to continue.

To configure a network connection manually, click the button Configure Network. The Network Connections dialog appears that allows you to configure wired, wireless, mobile broadband, VPN, and DSL connections for the system using the NetworkManager tool. A full description of all configurations possible with NetworkManager is beyond the scope of this guide. This section only details the most typical scenario of how to configure wired connections during installation. Configuration of other types of network is broadly similar, although the specific parameters that you must configure are necessarily different.

![Network Connections](image)

Figure 8.21. Network Connections

To add a new connection or to modify or remove a connection configured earlier in the installation process, click the tab that corresponds to the type of connection. To add a new connection of that type, click Add. To modify an existing connection, select it in the list and click Edit. In either case, a dialog box appears with a set of tabs that is appropriate to the particular connection type, as described below. To remove a connection, select it in the list and click Delete.

When you have finished editing network settings, click Apply to activate your changes. Note that re-configuring your network settings might require you to re-connect using the new settings.
8.9.1.1. Options common to all types of connection

Certain configuration options are common to all connection types.

Specify a name for the connection in the Connection name name field.

Select Start automatically to start the connection automatically when the system boots.

Select Available to all users to make the connection available to all users.

8.9.1.2. The Wired tab

Use the Wired tab to specify or change the media access control (MAC) address for the network adapter, and either set the maximum transmission unit (MTU, in bytes) that can pass through the interface.
8.9.1.3. The 802.1x Security tab
Use the 802.1x Security tab to configure 802.1X port-based network access control (PNAC). Select Use 802.1X security for this connection to enable access control, then specify details of your network. The configuration options include:

Authentication
Choose one of the following methods of authentication:

- **TLS** for Transport Layer Security
- **Tunneled TLS** for Tunneled Transport Layer Security, otherwise known as TTLS, or EAP-TTLS
- **Protected EAP (PEAP)** for Protected Extensible Authentication Protocol

Identity
Provide the identity of this server.

User certificate
Browse to a personal X.509 certificate file encoded with Distinguished Encoding Rules (DER) or Privacy Enhanced Mail (PEM).

CA certificate
Browse to a X.509 certificate authority certificate file encoded with Distinguished Encoding Rules (DER) or Privacy Enhanced Mail (PEM).

Private key
Browse to a private key file encoded with Distinguished Encoding Rules (DER), Privacy Enhanced Mail (PEM), or the Personal Information Exchange Syntax Standard (PKCS#12).

Private key password
The password for the private key specified in the Private key field. Select Show password to make the password visible as you type it.
8.9.1.4. The IPv4 Settings tab

Use the IPv4 Settings tab to configure the IPv4 parameters for the previously selected network connection.

Use the Method drop-down menu to specify which settings the system should attempt to obtain from a Dynamic Host Configuration Protocol (DHCP) service running on the network. Choose from the following options:

**Automatic (DHCP)**

IPv4 parameters are configured by the DHCP service on the network.
Automatic (DHCP) addresses only
The IPv4 address, netmask, and gateway address are configured by the DHCP service on the network, but DNS servers and search domains must be configured manually.

Manual
IPv4 parameters are configured manually for a static configuration.

Link-Local Only
A link-local address in the 169.254/16 range is assigned to the interface.

Shared to other computers
The system is configured to provide network access to other computers. The interface is assigned an address in the 10.42.x.1/24 range, a DHCP server and DNS server are started, and the interface is connected to the default network connection on the system with network address translation (NAT).

Disabled
IPv4 is disabled for this connection.

If you selected a method that requires you to supply manual parameters, enter details of the IP address for this interface, the netmask, and the gateway in the Addresses field. Use the Add and Delete buttons to add or remove addresses. Enter a comma-separated list of DNS servers in the DNS servers field, and a comma-separated list of domains in the Search domains field for any domains that you want to include in name server lookups.

Optionally, enter a name for this network connection in the DHCP client ID field. This name must be unique on the subnet. When you assign a meaningful DHCP client ID to a connection, it is easy to identify this connection when troubleshooting network problems.

Deselect the Require IPv4 addressing for this connection to complete check box to allow the system to make this connection on an IPv6-enabled network if IPv4 configuration fails but IPv6 configuration succeeds.
8.9.1.4.1. Editing IPv4 routes
Fedora configures a number of routes automatically based on the IP addresses of a device. To edit additional routes, click the Routes button. The Editing IPv4 routes dialog appears.
Click **Add** to add the IP address, netmask, gateway address, and metric for a new static route.

Select **Ignore automatically obtained routes** to make the interface use only the routes specified for it here.

Select **Use this connection only for resources on its network** to restrict connections only to the local network.

### 8.9.1.5. The IPv6 Settings tab

Use the **IPv6 Settings tab** tab to configure the IPv6 parameters for the previously selected network connection.

Use the **Method** drop-down menu to specify which settings the system should attempt to obtain from a Dynamic Host Configuration Protocol (DHCP) service running on the network. Choose from the following options:

**Ignore**
- IPv6 is ignored for this connection.

**Automatic**
- IPv6 parameters are configured by the DHCP service on the network.

**Automatic, addresses only**
- The IPv6 address, prefix, and gateway address are configured by the DHCP service on the network, but DNS servers and search domains must be configured manually.

**Manual**
- IPv6 parameters are configured manually for a static configuration.

**Link-Local Only**
- A link-local address with the fe80::/10 prefix is assigned to the interface.
If you selected a method that requires you to supply manual parameters, enter details of the IP address for this interface, the netmask, and the gateway in the Addresses field. Use the Add and Delete buttons to add or remove addresses. Enter a comma-separated list of DNS servers in the DNS servers field, and a comma-separated list of domains in the Search domains field for any domains that you want to include in name server lookups.

Optionally, enter a name for this network connection in the DHCP client ID field. This name must be unique on the subnet. When you assign a meaningful DHCP client ID to a connection, it is easy to identify this connection when troubleshooting network problems.

Deselect the Require IPv6 addressing for this connection to complete check box to allow the system to make this connection on an IPv4-enabled network if IPv6 configuration fails but IPv4 configuration succeeds.

Figure 8.26. The IPv6 Settings tab
8.9.1.5.1. Editing IPv6 routes
Fedora configures a number of routes automatically based on the IP addresses of a device. To edit additional routes, click the Routes button. The Editing IPv6 routes dialog appears.

Click Add to add the IP address, netmask, gateway address, and metric for a new static route.

Select Use this connection only for resources on its network to restrict connections only to the local network.

8.10. Time Zone Configuration
Set your time zone by selecting the city closest to your computer's physical location. Click on the map to zoom in to a particular geographical region of the world.

Specify a time zone even if you plan to use NTP (Network Time Protocol) to maintain the accuracy of the system clock.

From here there are two ways for you to select your time zone:

- Using your mouse, click on the interactive map to select a specific city (represented by a yellow dot). A red X appears indicating your selection.

- You can also scroll through the list at the bottom of the screen to select your time zone. Using your mouse, click on a location to highlight your selection.
Figure 8.28. Configuring the Time Zone

If Fedora is the only operating system on your computer, select **System clock uses UTC**. The system clock is a piece of hardware on your computer system. Fedora uses the timezone setting to determine the offset between the local time and UTC on the system clock. This behavior is standard for systems that use UNIX, Linux, and similar operating systems.

Click **Next** to proceed.

---

### Windows and the System Clock

Do not enable the **System clock uses UTC** option if your machine also runs Microsoft Windows. Microsoft operating systems change the BIOS clock to match local time rather than UTC. This may cause unexpected behavior under Fedora.

---

### Note

To change your time zone configuration after you have completed the installation, use the **Time and Date Properties Tool**.

Type the `system-config-date` command in a shell prompt to launch the **Time and Date Properties Tool**. If you are not root, it prompts you for the root password to continue.

To run the **Time and Date Properties Tool** as a text-based application, use the command `timeconfig`. 
8.11. Set the Root Password

Setting up a root account and password is one of the most important steps during your installation. The root account is used to install packages, upgrade RPMs, and perform most system maintenance. Logging in as root gives you complete control over your system.

Note

The root user (also known as the superuser) has complete access to the entire system; for this reason, logging in as the root user is best done *only* to perform system maintenance or administration.

Use the root account only for system administration. Create a non-root account for your general use and use the `su` command to change to root only when you need to perform tasks that require superuser authorization. These basic rules minimize the changes of a typo or an incorrect command doing damage to your system.

Note

To become root, type `su -` at the shell prompt in a terminal window and then press `Enter`. Then, enter the root password and press `Enter`. 
Chapter 8. Installing using anaconda

The installation program prompts you to set a root password\(^1\) for your system. *You cannot proceed to the next stage of the installation process without entering a root password.*

The root password must be at least six characters long; the password you type is not echoed to the screen. You must enter the password twice; if the two passwords do not match, the installation program asks you to enter them again.

You should make the root password something you can remember, but not something that is easy for someone else to guess. Your name, your phone number, qwerty, password, root, 123456, and anteater are all examples of bad passwords. Good passwords mix numerals with upper and lower case letters and do not contain dictionary words: Aard387vark or 420BMttNT, for example. Remember that the password is case-sensitive. If you write down your password, keep it in a secure place. However, it is recommended that you do not write down this or any password you create.

![Note]

Do not use one of the example passwords offered in this manual. Using one of these passwords could be considered a security risk.

To change your root password after you have completed the installation, use the **Root Password Tool**.

Type the `system-config-users` command in a shell prompt to launch the **User Manager**, a powerful user management and configuration tool. If you are not root, it prompts you for the root password to continue.

Enter the root password into the **Root Password** field. Fedora displays the characters as asterisks for security. Type the same password into the **Confirm** field to ensure it is set correctly. After you set the root password, select **Next** to proceed.

### 8.12. Assign Storage Devices

If you selected more than one storage device on the storage devices selection screen (refer to [Section 8.8, “Storage Devices”](#)), anaconda asks you to select which of these devices should be available for installation of the operating system, and which should only be attached to the file system for data storage. If you selected only one storage device, anaconda does not present you with this screen.

During installation, the devices that you identify here as being for data storage only are mounted as part of the file system, but are not partitioned or formatted.

---

\(^1\) A root password is the administrative password for your Fedora system. You should only log in as root when needed for system maintenance. The root account does not operate within the restrictions placed on normal user accounts, so changes made as root can have implications for your entire system.
Assign Storage Devices

The screen is split into two panes. The left pane contains a list of devices to be used for data storage only. The right pane contains a list of devices that are to be available for installation of the operating system.

Each list contains information about the devices to help you to identify them. A small drop-down menu marked with an icon is located to the right of the column headings. This menu allows you to select the types of data presented on each device. Reducing or expanding the amount of information presented might help you to identify particular devices.

Move a device from one list to the other by clicking on the device, then clicking either the button labeled with a left-pointing arrow to move it to the list of data storage devices or the button labeled with a right-pointing arrow to move it to the list of devices available for installation of the operating system.

The list of devices available as installation targets also includes a radio button beside each device. Use this radio button to specify the device that you want to use as the boot device for the system.

**Important — chain loading**

If any storage device contains a boot loader that will chain load the Fedora boot loader, include that storage device among the **Install Target Devices**. Storage devices that you identify as **Install Target Devices** remain visible to **anaconda** during boot loader configuration.

Storage devices that you identify as **Install Target Devices** on this screen are not automatically erased by the installation process unless you selected the **Use All Space** option on the partitioning screen (refer to **Section 8.15, “Disk Partitioning Setup”**).

When you have finished identifying devices to be used for installation, click **Next** to continue.
Chapter 8. Installing using anaconda

8.13. Initializing the Hard Disk

If no readable partition tables are found on existing hard disks, the installation program asks to initialize the hard disk. This operation makes any existing data on the hard disk unreadable. If your system has a brand new hard disk with no operating system installed, or you have removed all partitions on the hard disk, click Re-initialize drive.

The installation program presents you with a separate dialog for each disk on which it cannot read a valid partition table. Click the Ignore all button or Re-initialize all button to apply the same answer to all devices.

![Warning](image)

**Warning**

Error processing drive:
/dev/sda
20480MB

This device may need to be reinitialized.

REINITIALIZING WILL CAUSE ALL DATA TO BE LOST!

This action may also be applied to all other disks needing reinitialization.

Device details:
pci-0000:00:01.1-scsi-0:0:0:0

[Ignore] [Ignore all] [Re-initialize] [Re-initialize all]

Figure 8.31. Warning screen – initializing hard drive

Certain RAID systems or other nonstandard configurations may be unreadable to the installation program and the prompt to initialize the hard disk may appear. The installation program responds to the physical disk structures it is able to detect.

To enable automatic initializing of hard disks for which it turns out to be necessary, use the kickstart command `clearpart --initlabel` (refer to Chapter 14, Kickstart Installations)

---

**Detach Unneeded Disks**

If you have a nonstandard disk configuration that can be detached during installation and detected and configured afterward, power off the system, detach it, and restart the installation.
8.14. Upgrading an Existing System

Preupgrade

Fedora includes **preupgrade**, a command-line tool that allows you to upgrade easily to a new version from within your existing Fedora installation.

The installation system automatically detects any existing installation of Fedora. The upgrade process updates the existing system software with new versions, but does not remove any data from users’ home directories. The existing partition structure on your hard drives does not change. Your system configuration changes only if a package upgrade demands it. Most package upgrades do not change system configuration, but rather install an additional configuration file for you to examine later.

Note that the installation medium that you are using might not contain all the software packages that you need to upgrade your computer.

8.14.1. The Upgrade Dialog

If your system contains a Fedora installation, a dialog appears asking whether you want to upgrade that installation. To perform an upgrade of an existing system, choose the appropriate installation from the drop-down list and select **Next**.

![Figure 8.32. The Upgrade Dialog](image-url)
Manually Installed Software

Software you have installed manually on your existing Fedora system may behave differently after an upgrade. You may need to manually reinstall or recompile this software after an upgrade to ensure it performs correctly on the updated system.

8.14.2. Upgrading Using the Installer

Installations are Recommended

In general, Red Hat recommends that you keep user data on a separate /home partition and perform a fresh installation. For more information on partitions and how to set them up, refer to Section 8.15, “Disk Partitioning Setup”.

If you choose to upgrade your system using the installation program, any software not provided by Fedora that conflicts with Fedora software is overwritten. Before you begin an upgrade this way, make a list of your system’s current packages for later reference:

```
rpm -qa --qf '%{NAME} %{VERSION}-%{RELEASE} %{ARCH}\n' > ~/old-pkglist.txt
```

After installation, consult this list to discover which packages you may need to rebuild or retrieve from sources other than Red Hat.

Next, make a backup of any system configuration data:

```
su -c 'tar czf /tmp/etc-`date +%F`.tar.gz /etc'
su -c 'mv /tmp/etc-*.tar.gz /home'
```

Make a complete backup of any important data before performing an upgrade. Important data may include the contents of your entire /home directory as well as content from services such as an Apache, FTP, or SQL server, or a source code management system. Although upgrades are not destructive, if you perform one improperly there is a small possibility of data loss.

Storing Backups

Note that the above examples store backup materials in a /home directory. If your /home directory is not a separate partition, you should not follow these examples verbatim! Store your backups on another device such as CD or DVD discs or an external hard disk.

For more information on completing the upgrade process later, refer to Section 17.2, “Finishing an Upgrade”.

8.14.3. Upgrading Boot Loader Configuration

Your completed Fedora installation must be registered in the boot loader to boot properly. A boot loader is software on your machine that locates and starts the operating system. Refer to Appendix E, GRUB Boot Loader for more information about boot loaders.
The installer is unable to detect the boot loader currently in use on your system.

What would you like to do?

- Update boot loader configuration
  This will update your current boot loader.

- Skip boot loader updating
  This option makes no changes to boot loader configuration. If you are using a third party boot loader, you should choose this.

- Create new boot loader configuration
  This option creates a new boot loader configuration. If you wish to switch boot loaders, you should choose this.

Figure 8.33. The Upgrade Boot Loader Dialog

If the existing boot loader was installed by a Linux distribution, the installation system can modify it to load the new Fedora system. To update the existing Linux boot loader, select Update boot loader configuration. This is the default behavior when you upgrade an existing Fedora installation.

GRUB is the standard boot loader for Fedora on 32-bit and 64-bit x86 architectures. If your machine uses another boot loader, such as BootMagic, System Commander, or the loader installed by Microsoft Windows, then the Fedora installation system cannot update it. In this case, select Skip boot loader updating. When the installation process completes, refer to the documentation for your product for assistance.

Install a new boot loader as part of an upgrade process only if you are certain you want to replace the existing boot loader. If you install a new boot loader, you may not be able to boot other operating systems on the same machine until you have configured the new boot loader. Select Create new boot loader configuration to remove the existing boot loader and install GRUB.

After you make your selection, click Next to continue. If you selected the Create new boot loader configuration option, refer to Section 8.19, “x86, AMD64, and Intel 64 Boot Loader Configuration”. If you chose to update or skip boot loader configuration, installation continues without further input from you.

8.15. Disk Partitioning Setup

Warning — Back up your data

It is always a good idea to back up any data that you have on your systems. For example, if you are upgrading or creating a dual-boot system, you should back up any data you wish to keep on your storage devices. Mistakes do happen and can result in the loss of all your data.
## Important — Installing in text mode

If you install Fedora in text mode, you can only use the default partitioning schemes described in this section. You cannot add or remove partitions or file systems beyond those that the installer automatically adds or removes. If you require a customized layout at installation time, you should perform a graphical installation over a VNC connection or a kickstart installation.

Furthermore, advanced options such as LVM, encrypted filesystems, and resizable filesystems are available only in graphical mode and kickstart.

## Important — Booting from RAIDs

If you have a RAID card, be aware that some BIOSes do not support booting from the RAID card. In cases such as these, the `/boot/` partition must be created on a partition outside of the RAID array, such as on a separate hard drive. An internal hard drive is necessary to use for partition creation with problematic RAID cards.

A `/boot/` partition is also necessary for software RAID setups.

If you have chosen to automatically partition your system, you should select **Review** and manually edit your `/boot/` partition.

Partitioning allows you to divide your hard drive into isolated sections, where each section behaves as its own hard drive. Partitioning is particularly useful if you run multiple operating systems. If you are not sure how you want your system to be partitioned, read *Appendix A, An Introduction to Disk Partitions* for more information.

---

### Which type of installation would you like?

- **Use All Space**
  - Removes all partitions on the selected device(s). This includes partitions created by other operating systems.
  - **Tip:** This option will remove data from the selected device(s). Make sure you have backups.

- **Replace Existing Linux System(s)**
  - Removes only Linux partitions (created from a previous Linux installation). This does not remove other partitions you may have on your storage device(s) (such as VFAT or FAT32).
  - **Tip:** This option will remove data from the selected device(s). Make sure you have backups.

- **Shrink Current System**
  - Shrinks existing partitions to create free space for the default layout.

- **Use Free Space**
  - Retains your current data and partitions and uses only the unpartitioned space on the selected device(s), assuming you have enough free space available.

- **Create Custom Layout**
  - Manually create your own custom layout on the selected device(s) using our partitioning tool.

- **Encrypt System**
- **Review and modify partitioning layout**
On this screen you can choose to create the default partition layout in one of four different ways, or choose to partition storage devices manually to create a custom layout.

The first four options allow you to perform an automated installation without having to partition your storage devices yourself. If you do not feel comfortable with partitioning your system, choose one of these options and let the installation program partition the storage devices for you. Depending on the option that you choose, you can still control what data (if any) is removed from the system.

Your options are:

Use All Space
Select this option to remove all partitions on your hard drives (this includes partitions created by other operating systems such as Windows VFAT or NTFS partitions).

⚠️ Warning
If you select this option, all data on the selected hard drives is removed by the installation program. Do not select this option if you have information that you want to keep on the hard drives where you are installing Fedora.

In particular, do not select this option when you configure a system to chain load the Fedora boot loader from another boot loader.

Replace Existing Linux System(s)
Select this option to remove only partitions created by a previous Linux installation. This does not remove other partitions you may have on your hard drives (such as VFAT or FAT32 partitions).

Shrink Current System
Select this option to resize your current data and partitions manually and install a default Fedora layout in the space that is freed.

⚠️ Warning
If you shrink partitions on which other operating systems are installed, you might not be able to use those operating systems. Although this partitioning option does not destroy data, operating systems typically require some free space in their partitions. Before you resize a partition that holds an operating system that you might want to use again, find out how much space you need to leave free.

Use Free Space
Select this option to retain your current data and partitions and install Fedora in the unused space available on the storage drives. Ensure that there is sufficient space available on the storage drives before you select this option — refer to Section 4.4, "Do You Have Enough Disk Space?".

Create Custom Layout
Select this option to partition storage devices manually and create customized layouts. Refer to Section 8.17, "Creating a Custom Layout or Modifying the Default Layout"

Choose your preferred partitioning method by clicking the radio button to the left of its description in the dialog box.

Select Encrypt system to encrypt all partitions except the /boot partition. Refer to Appendix C, Disk Encryption for information on encryption.
Chapter 8. Installing using anaconda

To review and make any necessary changes to the partitions created by automatic partitioning, select the Review option. After selecting Review and clicking Next to move forward, the partitions created for you by anaconda appear. You can make modifications to these partitions if they do not meet your needs.

Important — chain loading

To configure the Fedora boot loader to chain load from a different boot loader, you must specify the boot drive manually. If you chose any of the automatic partitioning options, you must now select the Review and modify partitioning layout option before you click Next or you cannot specify the correct boot drive.

Click Next once you have made your selections to proceed.

8.16. Encrypt Partitions

If you selected the Encrypt System option, the installer prompts you for a passphrase with which to encrypt the partitions on the system.

Partitions are encrypted using the Linux Unified Key Setup — refer to Appendix C, Disk Encryption for more information.

Figure 8.35. Enter passphrase for encrypted partition

Choose a passphrase and type it into each of the two fields in the dialog box. You must provide this passphrase every time that the system boots.

Warning — Do not lose this passphrase

If you lose this passphrase, any encrypted partitions and the data on them will become completely inaccessible. There is no way to recover a lost passphrase.

Note that if you perform a kickstart installation of Fedora, you can save encryption passphrases and create backup encryption passphrases during installation. Refer to Section C.3.2, “Saving Passphrases” and Section C.3.3, “Creating and Saving Backup Passphrases”.

80
8.17. Creating a Custom Layout or Modifying the Default Layout

If you chose one of the four automatic partitioning options and did not select **Review**, skip ahead to Section 8.20, “Package Group Selection”.

If you chose one of the automatic partitioning options and selected **Review**, you can either accept the current partition settings (click **Next**), or modify the setup manually in the partitioning screen.

If you chose to create a custom layout, you must tell the installation program where to install Fedora. This is done by defining mount points for one or more disk partitions in which Fedora is installed. You may also need to create and/or delete partitions at this time.

If you have not yet planned how to set up your partitions, refer to Appendix A, An Introduction to Disk Partitions and Section 8.17.5, “Recommended Partitioning Scheme”. At a bare minimum, you need an appropriately-sized root partition, and usually a swap partition appropriate to the amount of RAM you have on the system.

**Anaconda** can handle the partitioning requirements for a typical installation.

![Partitioning on x86, AMD64, and Intel 64 Systems](image)

The partitioning screen contains two panes. The top pane contains a graphical representation of the hard drive, logical volume, or RAID device selected in the lower pane.

Above the graphical representation of the device, you can review the name of the drive (such as `/dev/sda` or `LogVol00`), its size (in MB), and its model as detected by the installation program.

Using your mouse, click once to highlight a particular field in the graphical display. Double-click to edit an existing partition or to create a partition out of existing free space.

The lower pane contains a list of all drives, logical volumes, and RAID devices to be used during installation, as specified earlier in the installation process — refer to Section 8.12, “Assign Storage Devices”.
Chapter 8. Installing using anaconda

Devices are grouped by type. Click on the small triangles to the left of each device type to view or hide devices of that type.

**Anaconda** displays several details for each device listed:

Device
- the name of the device, logical volume, or partition

Size (MB)
- the size of the device, logical volume, or partition (in MB)

Mount Point/RAID/Volume
- the *mount point* (location within a file system) on which a partition is to be mounted, or the name of the RAID or logical volume group of which it is a part

Type
- the type of partition. If the partition is a standard partition, this field displays the type of file system on the partition (for example, ext4). Otherwise, it indicates that the partition is a **physical volume** (LVM), or part of a **software RAID**

Format
- A check mark in this column indicates that the partition will be formatted during installation.

Beneath the lower pane are four buttons: **Create**, **Edit**, **Delete**, and **Reset**.

Select a device or partition by clicking on it in either the graphical representation in the upper pane of in the list in the lower pane, then click one of the four buttons to carry out the following actions:

Create
- create a new partition, logical volume, or software RAID

Edit
- change an existing new partition, logical volume, or software RAID

Delete
- remove a partition, logical volume, or software RAID

Reset
- undo all changes made in this screen

### 8.17.1. Create Storage

The **Create Storage** dialog allows you to create new storage partitions, logical volumes, and software RAID.s. **Anaconda** presents options as available or unavailable depending on the storage already present on the system or configured to transfer to the system.
Create Storage

Create Partition
- **Standard Partition** — create a standard disk partition (as described in Appendix A, An Introduction to Disk Partitions) in unallocated space.

Create Software RAID
- **RAID Partition** — create a RAID formatted partition
- **RAID Device** — requires at least 2 free RAID formatted partitions
- **RAID Clone** — facilitates RAID device creation

Create LVM
- **LVM Volume Group** — requires at least 1 free LVM formatted partition
- **LVM Physical Volume** — create an LVM formatted partition
- **LVM Logical Volume** — create a logical volume on a selected volume group

Options are grouped under **Create Partition**, **Create Software RAID** and **Create LVM** as follows:

**Create Partition**
Refer to Section 8.17.2, “Adding Partitions” for details of the **Add Partition** dialog.

- **Standard Partition** — create a standard disk partition (as described in Appendix A, An Introduction to Disk Partitions) in unallocated space.

**Create Software RAID**
Refer to Section 8.17.3, “Create Software RAID” for more detail.

- **RAID Partition** — create a partition in unallocated space to form part of a software RAID device. To form a software RAID device, two or more RAID partitions must be available on the system.
- **RAID Device** — combine two or more RAID partitions into a software RAID device. When you choose this option, you can specify the type of RAID device to create (the RAID level). This option is only available when two or more RAID partitions are available on the system.
- **RAID Clone** — create a mirror of a RAID partition on one storage device on another storage device. This option is only available when at least one RAID partition is available on the system.

**Create LVM Logical Volume**
Refer to Section 8.17.4, “Create LVM Logical Volume” for more detail.

- **LVM Physical Volume** — create a physical volume in unallocated space.
- **LVM Volume Group** — create a volume group from one or more physical volumes. This option is only available when at least one physical volume is available on the system.
• **LVM Logical Volume** — create a *logical volume* on a volume group. This option is only available when at least one volume group is available on the system.

### 8.17.2. Adding Partitions

To add a new partition, select the **Create** button. A dialog box appears (refer to Figure 8.38, "Creating a New Partition").

**Note**

You must dedicate at least one partition for this installation, and optionally more. For more information, refer to *Appendix A, An Introduction to Disk Partitions*.

![Add Partition](image)

**Figure 8.38. Creating a New Partition**

- **Mount Point**: Enter the partition's mount point. For example, if this partition should be the root partition, enter `/`; enter `/boot` for the `/boot` partition, and so on. You can also use the pull-down menu to choose the correct mount point for your partition. For a swap partition the mount point should not be set — setting the filesystem type to *swap* is sufficient.

- **File System Type**: Using the pull-down menu, select the appropriate file system type for this partition. For more information on file system types, refer to *Section 8.17.2.1, “File System Types”*. 
Adding Partitions

• **Allowable Drives**: This field contains a list of the hard disks installed on your system. If a hard disk’s box is highlighted, then a desired partition can be created on that hard disk. If the box is not checked, then the partition will never be created on that hard disk. By using different checkbox settings, you can have anaconda place partitions where you need them, or let anaconda decide where partitions should go.

• **Size (MB)**: Enter the size (in megabytes) of the partition. Note, this field starts with 200 MB; unless changed, only a 200 MB partition will be created.

• **Additional Size Options**: Choose whether to keep this partition at a fixed size, to allow it to “grow” (fill up the available hard drive space) to a certain point, or to allow it to grow to fill any remaining hard drive space available.

If you choose **Fill all space up to (MB)**, you must give size constraints in the field to the right of this option. This allows you to keep a certain amount of space free on your hard drive for future use.

• **Force to be a primary partition**: Select whether the partition you are creating should be one of the first four partitions on the hard drive. If unselected, the partition is created as a logical partition. Refer to Section A.1.3, “Partitions within Partitions — An Overview of Extended Partitions”, for more information.

• **Encrypt**: Choose whether to encrypt the partition so that the data stored on it cannot be accessed without a passphrase, even if the storage device is connected to another system. Refer to Appendix C, Disk Encryption for information on encryption of storage devices. If you select this option, the installer prompts you to provide a passphrase before it writes the partition to the disk.

• **OK**: Select OK once you are satisfied with the settings and wish to create the partition.

• **Cancel**: Select Cancel if you do not want to create the partition.

### 8.17.2.1. File System Types

Fedora allows you to create different partition types and file systems. The following is a brief description of the different partition types and file systems available, and how they can be used.

**Partition types**

• **standard partition** — A standard partition can contain a file system or swap space, or it can provide a container for software RAID or an LVM physical volume.

• **swap** — Swap partitions are used to support virtual memory. In other words, data is written to a swap partition when there is not enough RAM to store the data your system is processing. Refer to the Fedora Deployment Guide for additional information.

• **software RAID** — Creating two or more software RAID partitions allows you to create a RAID device. For more information regarding RAID, refer to the chapter RAID (Redundant Array of Independent Disks) in the Fedora Deployment Guide.

• **physical volume (LVM)** — Creating one or more physical volume (LVM) partitions allows you to create an LVM logical volume. LVM can improve performance when using physical disks. For more information regarding LVM, refer to the Fedora Deployment Guide.

**File systems**

• **ext4** — The ext4 file system is based on the ext3 file system and features a number of improvements. These include support for larger file systems and larger files, faster and more efficient allocation of disk space, no limit on the number of subdirectories within a directory, faster file system checking, and more robust journalling. The ext4 file system is selected by default and is highly recommended.
Chapter 8. Installing using anaconda

- **ext3** — The ext3 file system is based on the ext2 file system and has one main advantage — journaling. Using a journaling file system reduces time spent recovering a file system after a crash as there is no need to `fsck` the file system.

- **ext2** — An ext2 file system supports standard Unix file types (regular files, directories, symbolic links, etc). It provides the ability to assign long file names, up to 255 characters.

- **xfs** — XFS is a highly scalable, high-performance file system that supports filesystems up to 16 exabytes (approximately 16 million terabytes), files up to 8 exabytes (approximately 8 million terabytes) and directory structures containing tens of millions of entries. XFS supports metadata journaling, which facilitates quicker crash recovery. The XFS file system can also be defragmented and resized while mounted and active.

- **vfat** — The VFAT file system is a Linux file system that is compatible with Microsoft Windows long filenames on the FAT file system.

- **Btrfs** — Btrfs is under development as a file system capable of addressing and managing more files, larger files, and larger volumes than the ext2, ext3, and ext4 file systems. Btrfs is designed to make the file system tolerant of errors, and to facilitate the detection and repair of errors when they occur. It uses checksums to ensure the validity of data and metadata, and maintains snapshots of the file system that can be used for backup or repair.

Because Btrfs is still experimental and under development, the installation program does not offer it by default. If you want to create a Btrfs partition on a drive, you must commence the installation process with the boot option `btrfs`. Refer to *Chapter 10, Boot Options* for instructions.

"Btrfs is still experimental"

Fedora 14 includes Btrfs as a technology preview to allow you to experiment with this file system. You should not choose Btrfs for partitions that will contain valuable data or that are essential for the operation of important systems.

### 8.17.3. Create Software RAID

Redundant arrays of independent disks (RAIDs) are constructed from multiple storage devices that are arranged to provided increased performance and — in some configurations — greater fault tolerance. Refer to the *Fedora Deployment Guide* for a description of different kinds of RAIDs.

To make a RAID device, you must first create software RAID partitions. Once you have created two or more software RAID partitions, select **RAID** to join the software RAID partitions into a RAID device.

**RAID Partition**

Choose this option to configure a partition for software RAID. This option is the only choice available if your disk contains no software RAID partitions. This is the same dialog that appears when you add a standard partition — refer to *Section 8.17.2, “Adding Partitions”* for a description of the available options. Note, however, that **File System Type** must be set to **software RAID**.
RAID Device
Choose this option to construct a RAID device from two or more existing software RAID partitions. This option is available if two or more software RAID partitions have been configured.
Select the file system type as for a standard partition.

**Anaconda** automatically suggests a name for the RAID device, but you can manually select names from `md0` to `md15`.

Click the checkboxes beside individual storage devices to include or remove them from this RAID.

The **RAID Level** corresponds to a particular type of RAID. Choose from the following options:

- **RAID 0** — distributes data across multiple storage devices. Level 0 RAIDs offer increased performance over standard partitions, and can be used to pool the storage of multiple devices into one large virtual device. Note that Level 0 RAIDS offer no redundancy and that the failure of one device in the array destroys the entire array. RAID 0 requires at least two RAID partitions.

- **RAID 1** — mirrors the data on one storage device onto one or more other storage devices. Additional devices in the array provide increasing levels of redundancy. RAID 1 requires at least two RAID partitions.

- **RAID 4** — distributes data across multiple storage devices, but uses one device in the array to store parity information that safeguards the array in case any device within the array fails. Because all parity information is stored on the one device, access to this device creates a bottleneck in the performance of the array. RAID 4 requires at least three RAID partitions.

- **RAID 5** — distributes data and parity information across multiple storage devices. Level 5 RAIDs therefore offer the performance advantages of distributing data across multiple devices, but do not share the performance bottleneck of level 4 RAIDs because the parity information is also distributed through the array. RAID 5 requires at least three RAID partitions.

- **RAID 6** — level 6 RAIDs are similar to level 5 RAIDs, but instead of storing only one set of parity data, they store two sets. RAID 6 requires at least four RAID partitions.

- **RAID 10** — level 10 RAIDs are nested RAIDs or hybrid RAIDs. Level 10 RAIDs are constructed by distributing data over mirrored sets of storage devices. For example, a level 10 RAID constructed from four RAID partitions consists of two pairs of partitions in which one partition mirrors the other. Data is then distributed across both pairs of storage devices, as in a level 0 RAID. RAID 10 requires at least four RAID partitions.

**RAID Clone**

Choose this option to set up a RAID *mirror* of an existing disk. This option is available if two or more disks are attached to the system.
8.17.4. Create LVM Logical Volume

Important — LVM Unavailable in Text-Mode Installations

LVM initial set up is not available during text-mode installation. If you need to create an LVM configuration from scratch, press `Alt+F2` to use a different virtual console, and run the `lvm` command. To return to the text-mode installation, press `Alt+F1`.

Logical Volume Management (LVM) presents a simple logical view of underlying physical storage space, such as a hard drives or LUNs. Partitions on physical storage are represented as physical volumes that can be grouped together into volume groups. Each volume group can be divided into multiple logical volumes, each of which is analogous to a standard disk partition. Therefore, LVM logical volumes function as partitions that can span multiple physical disks.

To read more about LVM, refer to the Fedora Deployment Guide. Note, LVM is only available in the graphical installation program.

LVM Physical Volume

Choose this option to configure a partition or device as an LVM physical volume. This option is the only choice available if your storage does not already contain LVM Volume Groups. This is the same dialog that appears when you add a standard partition — refer to Section 8.17.2, “Adding
Partitions for a description of the available options. Note, however, that File System Type must be set to physical volume (LVM).

![Add Partition](image)

**Figure 8.42. Create an LVM Physical Volume**

**Make LVM Volume Group**

Choose this option to create LVM volume groups from the available LVM physical volumes, or to add existing logical volumes to a volume group.
To assign one or more physical volumes to a volume group, first name the volume group. Then select the physical volumes to be used in the volume group. Finally, configure logical volumes on any volume groups using the Add, Edit and Delete options.

You may not remove a physical volume from a volume group if doing so would leave insufficient space for that group's logical volumes. Take for example a volume group made up of two 5 GB LVM physical volume partitions, which contains an 8 GB logical volume. The installer would not allow you to remove either of the component physical volumes, since that would leave only 5 GB in the group for an 8 GB logical volume. If you reduce the total size of any logical volumes appropriately, you may then remove a physical volume from the volume group. In the example, reducing the size of the logical volume to 4 GB would allow you to remove one of the 5 GB physical volumes.

Make Logical Volume
Choose this option to create an LVM logical volume. Select a mount point, file system type, and size (in MB) just as if it were a standard disk partition. You can also choose a name for the logical volume and specify the volume group to which it will belong.
8.17.5. Recommended Partitioning Scheme

8.17.5.1. x86, AMD64, and Intel 64 systems

Unless you have a reason for doing otherwise, we recommend that you create the following partitions for x86, AMD64, and Intel 64 systems:

- A swap partition
- A `/boot` partition
- A `/` partition
- A swap partition (at least 256 MB) — swap partitions are used to support virtual memory. In other words, data is written to a swap partition when there is not enough RAM to store the data your system is processing.

In years past, the recommended amount of swap space increased linearly with the amount of RAM in the system. But because the amount of memory in modern systems has increased into the hundreds of gigabytes, it is now recognized that the amount of swap space that a system needs is a function of the memory workload running on that system. However, given that swap space is usually designated at install time, and that it can be difficult to determine beforehand the memory workload of a system, we recommend determining system swap using the following table.

<table>
<thead>
<tr>
<th>Amount of RAM in the System</th>
<th>Recommended Amount of Swap Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>4GB of RAM or less</td>
<td>a minimum of 2GB of swap space</td>
</tr>
<tr>
<td>4GB to 16GB of RAM</td>
<td>a minimum of 4GB of swap space</td>
</tr>
<tr>
<td>16GB to 64GB of RAM</td>
<td>a minimum of 8GB of swap space</td>
</tr>
<tr>
<td>64GB to 256GB of RAM</td>
<td>a minimum of 16GB of swap space</td>
</tr>
<tr>
<td>256GB to 512GB of RAM</td>
<td>a minimum of 32GB of swap space</td>
</tr>
</tbody>
</table>

Note that you can obtain better performance by distributing swap space over multiple storage devices, particularly on systems with fast drives, controllers, and interfaces.
• **A /boot/ partition (250 MB)**
The partition mounted on /boot/ contains the operating system kernel (which allows your system to boot Fedora), along with files used during the bootstrap process. For most users, a 250 MB boot partition is sufficient.

### Important — Supported file systems

The **GRUB** bootloader in Fedora 14 supports only the ext2, ext3, and ext4 (recommended) file systems. You cannot use any other file system for /boot, such as Btrfs, XFS, or VFAT.

### Note

If your hard drive is more than 1024 cylinders (and your system was manufactured more than two years ago), you may need to create a /boot/ partition if you want the / (root) partition to use all of the remaining space on your hard drive.

### Note

If you have a RAID card, be aware that some BIOSes do not support booting from the RAID card. In cases such as these, the /boot/ partition must be created on a partition outside of the RAID array, such as on a separate hard drive.

• **A root partition (3.0 GB - 5.0 GB)**

This is where “/” (the root directory) is located. In this setup, all files (except those stored in /boot) are on the root partition.

A 3.0 GB partition allows you to install a minimal installation, while a 5.0 GB root partition lets you perform a full installation, choosing all package groups.

### Root and /root

The / (or root) partition is the top of the directory structure. The /root directory/root (sometimes pronounced “slash-root”) directory is the home directory of the user account for system administration.

Many systems have more partitions than the minimum listed above. Choose partitions based on your particular system needs. For example, consider creating a separate /home partition on systems that store user data. Refer to Section 8.17.5.1.1, “Advice on Partitions” for more information.

If you create many partitions instead of one large / partition, upgrades become easier. Refer to the description of the Edit option in Section 8.17, “Creating a Custom Layout or Modifying the Default Layout” for more information.
Chapter 8. Installing using anaconda

if the partition containing /foo must be at least 500 MB, and you do not make a separate /foo partition, then the / (root) partition must be at least 500 MB.

Table 8.4. Minimum partition sizes

<table>
<thead>
<tr>
<th>Directory</th>
<th>Minimum size</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>250 MB</td>
</tr>
<tr>
<td>/usr</td>
<td>250 MB, but avoid placing this on a separate partition</td>
</tr>
<tr>
<td>/tmp</td>
<td>50 MB</td>
</tr>
<tr>
<td>/var</td>
<td>384 MB</td>
</tr>
<tr>
<td>/home</td>
<td>100 MB</td>
</tr>
<tr>
<td>/boot</td>
<td>250 MB</td>
</tr>
</tbody>
</table>

Leave Excess Capacity Unallocated

Only assign storage capacity to those partitions you require immediately. You may allocate free space at any time, to meet needs as they occur. To learn about a more flexible method for storage management, refer to Appendix D, Understanding LVM.

Important — Supported file systems

The GRUB bootloader in Fedora 14 supports only the ext2, ext3, and ext4 (recommended) file systems. You cannot use any other file system for /boot, such as Btrfs, XFS, or VFAT.

• The /var directory holds content for a number of applications, including the Apache web server. It also is used to store downloaded update packages on a temporary basis. Ensure that the partition containing the /var directory has enough space to download pending updates and hold your other content.
The PackageKit update software downloads updated packages to /var/cache/yum/ by default. If you partition the system manually, and create a separate /var/ partition, be sure to create the partition large enough (3.0 GB or more) to download package updates.

• The /usr directory holds the majority of software content on a Fedora system. For an installation of the default set of software, allocate at least 4 GB of space. If you are a software developer or plan to use your Fedora system to learn software development skills, you may want to at least double this allocation.

Do not place /usr on a separate partition

If /usr is on a separate partition from /, the boot process becomes much more complex, and in some situations (like installations on iSCSI drives), might not work at all.

• Consider leaving a portion of the space in an LVM volume group unallocated. This unallocated space gives you flexibility if your space requirements change but you do not wish to remove data from other partitions to reallocate storage.

• If you separate subdirectories into partitions, you can retain content in those subdirectories if you decide to install a new version of Fedora over your current system. For instance, if you intend to run a MySQL database in /var/lib/mysql, make a separate partition for that directory in case you need to reinstall later.

The following table is a possible partition setup for a system with a single, new 80 GB hard disk and 1 GB of RAM. Note that approximately 10 GB of the volume group is unallocated to allow for future growth.

Example Usage

This setup is not optimal for all use cases.

Example 8.1. Example partition setup

Table 8.5. Example partition setup

<table>
<thead>
<tr>
<th>Partition</th>
<th>Size and type</th>
</tr>
</thead>
<tbody>
<tr>
<td>/boot</td>
<td>250 MB ext3 partition</td>
</tr>
<tr>
<td>swap</td>
<td>2 GB swap</td>
</tr>
<tr>
<td>LVM physical volume</td>
<td>Remaining space, as one LVM volume group</td>
</tr>
</tbody>
</table>

The physical volume is assigned to the default volume group and divided into the following logical volumes:
Table 8.6. Example partition setup: LVM physical volume

<table>
<thead>
<tr>
<th>Partition</th>
<th>Size and type</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>13 GB ext4</td>
</tr>
<tr>
<td>/var</td>
<td>4 GB ext4</td>
</tr>
<tr>
<td>/home</td>
<td>50 GB ext4</td>
</tr>
</tbody>
</table>

8.18. Write changes to disk

The installer prompts you to confirm the partitioning options that you selected. Click **Write changes to disk** to allow the installer to partition your hard drive and install Fedora.

![Writing storage configuration to disk](image)

If you are certain that you want to proceed, click **Write changes to disk**.

**Last chance to cancel safely**

Up to this point in the installation process, the installer has made no lasting changes to your computer. When you click **Write changes to disk**, the installer will allocate space on your hard drive and start to transfer Fedora into this space. Depending on the partitioning option that you chose, this process might include erasing data that already exists on your computer.

To revise any of the choices that you made up to this point, click **Go back**. To cancel installation completely, switch off your computer. To switch off most computers at this stage, press the power button and hold it down for a few seconds.

After you click **Write changes to disk**, allow the installation process to complete. If the process is interrupted (for example, by you switching off or resetting the computer, or by a power outage) you will probably not be able to use your computer until you restart and complete the Fedora installation process, or install a different operating system.

8.19. x86, AMD64, and Intel 64 Boot Loader Configuration

To boot the system without boot media, you usually need to install a boot loader. A boot loader is the first software program that runs when a computer starts. It is responsible for loading and transferring control to the operating system kernel software. The kernel, in turn, initializes the rest of the operating system.

**Installing in text mode**

If you install Fedora in text mode, the installer configures the bootloader automatically and you cannot customize bootloader settings during the installation process.
GRUB (GRand Unified Bootloader), which is installed by default, is a very powerful boot loader. GRUB can load a variety of free operating systems, as well as proprietary operating systems with chain-loading (the mechanism for loading unsupported operating systems, such as Windows, by loading another boot loader). Note that the version of GRUB in Fedora 14 is an old and stable version now known as “GRUB Legacy” since upstream development moved to GRUB 2.\(^3\)

### The GRUB boot menu

The GRUB menu defaults to being hidden, except on dual-boot systems. To show the GRUB menu during system boot, press and hold the **Shift** key before the kernel is loaded. (Any other key works as well but the **Shift** key is the safest to use.)

![GRUB boot menu](http://www.gnu.org/software/grub/grub-legacy.en.html)

If there are no other operating systems on your computer, or you are completely removing any other operating systems the installation program will install **GRUB** as your boot loader without any intervention. In that case you may continue on to *Section 8.20, “Package Group Selection”*. You may have a boot loader installed on your system already. An operating system may install its own preferred boot loader, or you may have installed a third-party boot loader. If your boot loader does not recognize Linux partitions, you may not be able to boot Fedora. Use **GRUB** as your boot loader to boot Linux and most other operating systems. Follow the directions in this chapter to install **GRUB**.

---

\(^3\) [http://www.gnu.org/software/grub/grub-legacy.en.html](http://www.gnu.org/software/grub/grub-legacy.en.html)
Chapter 8. Installing using Anaconda

### Installing GRUB

If you install GRUB, it may overwrite your existing boot loader.

By default, the installation program installs GRUB in the master boot record or MBR, of the device for the root file system. To decline installation of a new boot loader, unselect **Install boot loader on /dev/sda**.

**Warning**

If you choose not to install GRUB for any reason, you will not be able to boot the system directly, and you must use another boot method (such as a commercial boot loader application). Use this option only if you are sure you have another way of booting the system!

If you have other operating systems already installed, Fedora attempts to automatically detect and configure GRUB to boot them. You may manually configure any additional operating systems if GRUB does not detect them.

To add, remove, or change the detected operating system settings, use the options provided.

**Add**

Select **Add** to include an additional operating system in GRUB.

Select the disk partition which contains the bootable operating system from the drop-down list and give the entry a label. GRUB displays this label in its boot menu.

**Edit**

To change an entry in the GRUB boot menu, select the entry and then select **Edit**.

**Delete**

To remove an entry from the GRUB boot menu, select the entry and then select **Delete**.

Select **Default** beside the preferred boot partition to choose your default bootable OS. You cannot move forward in the installation unless you choose a default boot image.

**Note**

The **Label** column lists what you must enter at the boot prompt, in non-graphical boot loaders, in order to boot the desired operating system.

Once you have loaded the GRUB boot screen, use the arrow keys to choose a boot label or type **e** for edit. You are presented with a list of items in the configuration file for the boot label you have selected.

Boot loader passwords provide a security mechanism in an environment where physical access to your server is available.

If you are installing a boot loader, you should create a password to protect your system. Without a boot loader password, users with access to your system can pass options to the kernel which can compromise your system security. With a boot loader password in place, the password must first be
entered before selecting any non-standard boot options. However, it is still possible for someone with physical access to the machine to boot from a diskette, CD-ROM, DVD, or USB media if the BIOS supports it. Security plans which include boot loader passwords should also address alternate boot methods.

### GRUB Passwords Not Required

You may not require a GRUB password if your system only has trusted operators, or is physically secured with controlled console access. However, if an untrusted person can get physical access to your computer's keyboard and monitor, that person can reboot the system and access GRUB. A password is helpful in this case.

If you choose to use a boot loader password to enhance your system security, be sure to select the checkbox labeled **Use a boot loader password**.

Once selected, enter a password and confirm it. GRUB stores the password in encrypted form, so it cannot be read or recovered. If you forget the boot password, boot the system normally and then change the password entry in the `/boot/grub/grub.conf` file. If you cannot boot, you may be able to use the "rescue" mode on the first Fedora installation disc to reset the GRUB password.

If you do need to change the GRUB password, use the `grub-md5-crypt` utility. For information on using this utility, use the command `man grub-md5-crypt` in a terminal window to read the manual pages.

### GRUB recognizes only the QWERTY keyboard layout

When selecting a GRUB password, be aware that GRUB recognizes only the QWERTY keyboard layout, regardless of the keyboard actually attached to the system. If you use a keyboard with a significantly different layout, it might be more effective to memorize a pattern of keystrokes rather than the word that the pattern produces.

To configure more advanced boot loader options, such as changing the drive order or passing options to the kernel, be sure **Configure advanced boot loader options** is selected before clicking **Next**.

### 8.19.1. Advanced Boot Loader Configuration

Now that you have chosen which boot loader to install, you can also determine where you want the boot loader to be installed. You may install the boot loader in one of two places:

- **The master boot record (MBR)** — This is the recommended place to install a boot loader, unless the MBR already starts another operating system loader, such as System Commander. The MBR is a special area on your hard drive that is automatically loaded by your computer's BIOS, and is the earliest point at which the boot loader can take control of the boot process. If you install it in the MBR, when your machine boots, GRUB presents a boot prompt. You can then boot Fedora or any other operating system that you have configured the boot loader to boot.

- **The first sector of your boot partition** — This is recommended if you are already using another boot loader on your system. In this case, your other boot loader takes control first. You can then configure that boot loader to start GRUB, which then boots Fedora.
If you install GRUB as a secondary boot loader, you must reconfigure your primary boot loader whenever you install and boot from a new kernel. The kernel of an operating system such as Microsoft Windows does not boot in the same fashion. Most users therefore use GRUB as the primary boot loader on dual-boot systems.

**Note**

If you have a RAID card, be aware that some BIOSes do not support booting from the RAID card. In cases such as these, the boot loader *should not* be installed on the MBR of the RAID array. Rather, the boot loader should be installed on the MBR of the same drive as the `/boot/` partition was created.

If your system only uses Fedora, you should choose the MBR.

Click the **Change Drive Order** button if you would like to rearrange the drive order or if your BIOS does not return the correct drive order. Changing the drive order may be useful if you have multiple SCSI adapters, or both SCSI and IDE adapters, and you want to boot from the SCSI device.

**Note**

While partitioning your hard drive, keep in mind that the BIOS in some older systems cannot access more than the first 1024 cylinders on a hard drive. If this is the case, leave enough room for the `/boot` Linux partition on the first 1024 cylinders of your hard drive to boot Linux. The other Linux partitions can be after cylinder 1024.

In *parted*, 1024 cylinders equals 528MB. For more information, refer to:

```html
http://www.pcguide.com/ref/hdd/bios/sizeMB504-c.html
```

### 8.19.2. Rescue Mode

Rescue mode provides the ability to boot a small Fedora environment entirely from boot media or some other boot method instead of the system's hard drive. There may be times when you are unable...
to get Fedora running completely enough to access files on your system’s hard drive. Using rescue mode, you can access the files stored on your system’s hard drive, even if you cannot actually run Fedora from that hard drive. If you need to use rescue mode, try the following method:

- Boot an x86, AMD64, or Intel 64 system from any installation medium, such as CD, DVD, USB, or PXE, and type `linux rescue` at the installation boot prompt. Refer to Chapter 18, Basic System Recovery for a more complete description of rescue mode.

For additional information, refer to the Fedora Deployment Guide.

### 8.19.3. Alternative Boot Loaders

**GRUB** is the default bootloader for Fedora, but is not the only choice. A variety of open-source and proprietary alternatives to **GRUB** are available to load Fedora, including **LILO**, **SYSLINUX**, **Acronis Disk Director Suite**, and **Apple Boot Camp**.

**Important**

Red Hat does not support third-party boot loaders.

### 8.20. Package Group Selection

Now that you have made most of the choices for your installation, you are ready to confirm the default package selection or customize packages for your system.

The **Package Installation Defaults** screen appears and details the default package set for your Fedora installation. This screen varies depending on the version of Fedora you are installing.

**Installing in text mode**

If you install Fedora in text mode, you cannot make package selections. The installer automatically selects packages only from the base and core groups. These packages are sufficient to ensure that the system is operational at the end of the installation process, ready to install updates and new packages. To change the package selection, complete the installation, then use the **Add/Remove Software** application to make desired changes.
Chapter 8. Installing using anaconda

The default installation of Fedora includes a set of software applicable for general internet usage. You can optionally select a different set of software now.

- **Graphical Desktop**
- **Software Development**
- **Web Server**
- **Minimal**

Please select any additional repositories that you want to use for software installation.

- [ ] Installation Repo
- [ ] Fedora 13-Beta - i386
- [ ] Fedora 13-Beta - i386 - Test Updates

You can further customize the software selection now, or after install via the software management application.

- [ ] Customize later
- [ ] Customize now

Figure 8.48. Package Group Selection

By default, the Fedora installation process loads a selection of software that is suitable for a system deployed as a basic server. Note that this installation does not include a graphical environment. To include a selection of software suitable for other roles, click the radio button that corresponds to one of the following options:

- **Graphical Desktop**
  - This option provides the [OpenOffice.org](http://openoffice.org) productivity suite, graphical tools such as the [GIMP](http://gimp.org), and multimedia applications.

- **Software Development**
  - This option provides the necessary tools to compile software on your Fedora system.

- **Web server**
  - This option provides the [Apache](http://apache.org) web server.

- **Minimal**
  - This option provides only the packages essential to run Fedora. A minimal installation provides the basis for a single-purpose server or desktop appliance and maximizes performance and security on such an installation.

If you choose to accept the current package list, skip ahead to Section 8.21, “Installing Packages”.

To select a component, click on the checkbox beside it (refer to Figure 8.48, “Package Group Selection”).

To customize your package set further, select the **Customize now** option on the screen. Clicking **Next** takes you to the Package Group Selection screen.

### 8.20.1. Installing from Additional Repositories

You can define additional repositories to increase the software available to your system during installation. A repository is a network location that stores software packages along with metadata that
describes them. Many of the software packages used in Fedora require other software to be installed. The installer uses the metadata to ensure that these requirements are met for every piece of software you select for installation.

The basic options are:

- The **Installation Repo** repository is automatically selected for you. This represents the collection of software available on your installation CD or DVD.

- The **Fedora 14 - i386** repository contains the complete collection of software that was released as Fedora 14, with the various pieces of software in their versions that were current at the time of release. If you are installing from the Fedora 14 DVD or set of CDs, this option does not offer you anything extra. However, if you are installing from a Fedora Live CD, this option provides access to far more software than is included on the disk. Note that the computer must have access to the internet to use this option.

- The **Fedora 14 - i386 - Updates** repository contains the complete collection of software that was released as Fedora 14, with the various pieces of software in their most current stable versions. This option not only installs the software that you select, but makes sure that it is fully updated as well. Note that the computer must have access to the internet to use this option.

![Edit Repository](image)

**Figure 8.49. Adding a software repository**

To include software from *repositories* other than the Fedora package collection, select **Add additional software repositories**. You may provide the location of a repository of third-party software. Depending on the configuration of that repository, you may be able to select non-Fedora software during installation.

To edit an existing software repository location, select the repository in the list and then select **Modify repository**.

**Network Access Required**

If you change the repository information during a non-network installation, such as from a Fedora DVD, the installer prompts you for network configuration information.
Chapter 8. Installing using anaconda

If you select **Add additional software repositories**, the **Edit repository** dialog appears. Provide a **Repository name** and the **Repository URL** for its location.

Fedora Software Mirrors

To find a Fedora software mirror near you, refer to [http://fedoraproject.org/wiki/Mirrors](http://fedoraproject.org/wiki/Mirrors).

Once you have located a mirror, to determine the URL to use, find the directory on the mirror that contains a directory named `repodata`. For instance, the “Everything” repository for Fedora is typically located in a directory tree `releases/14/Everything/arch/os`, where `arch` is a system architecture name.

Once you provide information for an additional repository, the installer reads the package metadata over the network. Software that is specially marked is then included in the package group selection system. See [Section 8.20.2, “Customizing the Software Selection”](#8202) for more information on selecting packages.

Backtracking Removes Repository Metadata

If you choose **Back** from the package selection screen, any extra repository data you may have entered is lost. This allows you to effectively cancel extra repositories. Currently there is no way to cancel only a single repository once entered.

8.20.2. Customizing the Software Selection

Additional Language Support

Your Fedora system automatically supports the language that you selected at the start of the installation process. To include support for additional languages, select the package group for those languages from the **Languages** category.

Select **Customize now** to specify the software packages for your final system in more detail. This option causes the installation process to display an additional customization screen when you select **Next**.
Fedora divides the included software into *package groups*. For ease of use, the package selection screen displays these groups as categories.

You can select package groups, which group components together according to function (for example, *X Window System* and *Editors*), individual packages, or a combination of the two.

To view the package groups for a category, select the category from the list on the left. The list on the right displays the package groups for the currently selected category.

To specify a package group for installation, select the check box next to the group. The box at the bottom of the screen displays the details of the package group that is currently highlighted. *None* of the packages from a group will be installed unless the check box for that group is selected.

If you select a package group, Fedora automatically installs the base and mandatory packages for that group. To change which optional packages within a selected group will be installed, select the *Optional Packages* button under the description of the group. Then use the check box next to an individual package name to change its selection.

In the package selection list on the right, you can use the context menu as a shortcut to select or deselect base and mandatory packages or all optional packages.
Your Fedora system automatically supports the language that you selected at the start of the installation process. To include support for additional languages, select the package group for those languages from the Languages category.

After you choose the desired packages, select Next to proceed. The installer checks your selection, and automatically adds any extra packages required to use the software you selected. When you have finished selecting packages, click Close to save your optional package selections and return to the main package selection screen.

The packages that you select are not permanent. After you boot your system, use the Add/Remove Software tool to either install new software or remove installed packages. To run this tool, from the main menu, select System → Administration → Add/Remove Software. The Fedora software management system downloads the latest packages from network servers, rather than using those on the installation discs.

### 8.20.2.1. Core Network Services

All Fedora installations include the following network services:

- centralized logging through syslog
- email through SMTP (Simple Mail Transfer Protocol)
- network file sharing through NFS (Network File System)
- remote access through SSH (Secure SHell)
- resource advertising through mDNS (multicast DNS)

The default installation also provides:

- network file transfer through HTTP (HyperText Transfer Protocol)
- printing through CUPS (Common UNIX Printing System)
- remote desktop access through VNC (Virtual Network Computing)

Some automated processes on your Fedora system use the email service to send reports and messages to the system administrator. By default, the email, logging, and printing services do not accept connections from other systems. Fedora installs the NFS sharing, HTTP, and VNC components without enabling those services.
You may configure your Fedora system after installation to offer email, file sharing, logging, printing and remote desktop access services. The SSH service is enabled by default. You may use NFS to access files on other systems without enabling the NFS sharing service.

### 8.21. Installing Packages

At this point there is nothing left for you to do until all the packages have been installed. How quickly this happens depends on the number of packages you have selected and your computer's speed.

Depending on the available resources, you might see the following progress bar while the installer resolves dependencies of the packages you selected for installation:

![Installation Starting](image)

Figure 8.52. Starting installation

Fedora reports the installation progress on the screen as it writes the selected packages to your system.

![Packages completed](image)

Figure 8.53. Packages completed

For your reference, a complete log of your installation can be found in `/root/install.log` once you reboot your system.

After installation completes, select Reboot to restart your computer. Fedora ejects any loaded discs before the computer reboots.

### 8.22. Installation Complete

Congratulations! Your Fedora installation is now complete!

The installation program prompts you to prepare your system for reboot. Remember to remove any installation media if it is not ejected automatically upon reboot.

After your computer's normal power-up sequence has completed, Fedora loads and starts. By default, the start process is hidden behind a graphical screen that displays a progress bar. Eventually, a `login:` prompt or a GUI login screen (if you installed the X Window System and chose to start X automatically) appears.

The first time you start your Fedora system in run level 5 (the graphical run level), the FirstBoot tool appears, which guides you through the Fedora configuration. Using this tool, you can set your system
time and date, install software, register your machine with Red Hat Network, and more. **FirstBoot** lets you configure your environment at the beginning, so that you can get started using your Fedora system quickly.
Troubleshooting Installation on an Intel or AMD System

This section discusses some common installation problems and their solutions.

For debugging purposes, anaconda logs installation actions into files in the /tmp directory. These files include:

/tmp/anaconda.log
  general anaconda messages

/tmp/program.log
  all external programs run by anaconda

/tmp/storage.log
  extensive storage module information

/tmp/yum.log
  yum package installation messages

/tmp/syslog
  hardware-related system messages

If the installation fails, the messages from these files are consolidated into /tmp/anacdump.txt.

All of the files above reside in the installer's ramdisk and are thus volatile. To make a permanent copy, copy those files to another system on the network using scp on the installation image (not the other way round).

9.1. You are unable to boot Fedora

9.1.1. Are You Unable to Boot With Your RAID Card?

If you have performed an installation and cannot boot your system properly, you may need to reinstall and create your partitions differently.

Some BIOSes do not support booting from RAID cards. At the end of an installation, a text-based screen showing the boot loader prompt (for example, GRUB: ) and a flashing cursor may be all that appears. If this is the case, you must repartition your system.

Whether you choose automatic or manual partitioning, you must install your /boot partition outside of the RAID array, such as on a separate hard drive. An internal hard drive is necessary to use for partition creation with problematic RAID cards.

You must also install your preferred boot loader (GRUB or LILO) on the MBR of a drive that is outside of the RAID array. This should be the same drive that hosts the /boot/ partition.

Once these changes have been made, you should be able to finish your installation and boot the system properly.
9.1.2. Is Your System Displaying Signal 11 Errors?
A signal 11 error, commonly known as a segmentation fault, means that the program accessed a memory location that was not assigned to it. A signal 11 error may be due to a bug in one of the software programs that is installed, or faulty hardware.

If you receive a fatal signal 11 error during your installation, it is probably due to a hardware error in memory on your system's bus. Like other operating systems, Fedora places its own demands on your system's hardware. Some of this hardware may not be able to meet those demands, even if they work properly under another OS.

Ensure that you have the latest installation updates and images. Review the online errata to see if newer versions are available. If the latest images still fail, it may be due to a problem with your hardware. Commonly, these errors are in your memory or CPU-cache. A possible solution for this error is turning off the CPU-cache in the BIOS, if your system supports this. You could also try to swap your memory around in the motherboard slots to check if the problem is either slot or memory related.

Another option is to perform a media check on your installation DVD. Anaconda, the installation program, has the ability to test the integrity of the installation media. It works with the DVD, hard drive ISO, and NFS ISO installation methods. Red Hat recommends that you test all installation media before starting the installation process, and before reporting any installation-related bugs (many of the bugs reported are actually due to improperly-burned DVDs). To use this test, type the following command at the boot: or yaboot: prompt:

```
linux mediacheck
```

For more information concerning signal 11 errors, refer to:

http://www.bitwizard.nl/sig11/

9.2. Trouble Beginning the Installation

9.2.1. Problems with Booting into the Graphical Installation
There are some video cards that have trouble booting into the graphical installation program. If the installation program does not run using its default settings, it tries to run in a lower resolution mode. If that still fails, the installation program attempts to run in text mode.

One possible solution is to use only a basic video driver during installation. You can do this either by selecting Install system with basic video driver on the boot menu, or using the xdriver=vesa boot option at the boot prompt. Alternatively, you can force the installer to use a specific screen resolution with the resolution= boot option. This option may be most helpful for laptop users. Another solution to try is the driver= option to specify the driver that should be loaded for your video card. If this works, you should report it as a bug, because the installer failed to detect your video card automatically. Refer to Chapter 10, Boot Options for more information on boot options.
Note

To disable frame buffer support and allow the installation program to run in text mode, try using the `nofb` boot option. This command may be necessary for accessibility with some screen reading hardware.

9.3. Trouble During the Installation

9.3.1. No devices found to install Fedora Error Message

If you receive an error message stating **No devices found to install Fedora**, there is probably a SCSI controller that is not being recognized by the installation program.

You can also refer to the Red Hat Hardware Compatibility List, available online at:

http://hardware.redhat.com/hcl/

9.3.2. Saving traceback messages

If **anaconda** encounters an error during the graphical installation process, it presents you with a crash reporting dialog box:

<table>
<thead>
<tr>
<th>Exception Occurred</th>
</tr>
</thead>
<tbody>
<tr>
<td>An unhandled exception has occurred. This is most likely a bug. Please save a copy of the detailed exception and file a bug report.</td>
</tr>
</tbody>
</table>

Details

Figure 9.1. The Crash Reporting Dialog Box

Details shows you the details of the error:
Chapter 9. Troubleshooting Installation on an Intel or AMD System

Figure 9.2. Details of the Crash

Save

saves details of the error locally or remotely:

Exit installer

exits the installation process.
If you select **Save** from the main dialog, you can choose from the following options:

**Local disk**

saves details of the error to the local hard drive, in a directory that you select with the file browser:

![Figure 9.3. Save Crash Report to a Local disk](image)

**Bugzilla**

submits details of the error to Red Hat's bug-tracking system, Bugzilla. You must supply an existing Bugzilla username and password, and a description of the bug.

![Figure 9.4. Save Crash Report to Bugzilla](image)

**Remote server**

saves details of the error to a remote location using **SCP**. You must specify the username, password, host, and destination file.

![Figure 9.5. Save Crash Report to Remote Server](image)
Chapter 9. Troubleshooting Installation on an Intel or AMD System

9.3.3. Trouble with Partition Tables
If you receive an error after the Disk Partitioning Setup (Section 8.15, "Disk Partitioning Setup") phase of the installation saying something similar to

The partition table on device hda was unreadable. To create new partitions it must be initialized, causing the loss of ALL DATA on this drive.

you may not have a partition table on that drive or the partition table on the drive may not be recognizable by the partitioning software used in the installation program.

Users who have used programs such as EZ-BIOS have experienced similar problems, causing data to be lost (assuming the data was not backed up before the installation began) that could not be recovered.

No matter what type of installation you are performing, backups of the existing data on your systems should always be made.

9.3.4. Using Remaining Space
You have a swap and a / (root) partition created, and you have selected the root partition to use the remaining space, but it does not fill the hard drive.

If your hard drive is more than 1024 cylinders, you must create a /boot partition if you want the / (root) partition to use all of the remaining space on your hard drive.

9.3.5. Other Partitioning Problems
If you create partitions manually, but cannot move to the next screen, you probably have not created all the partitions necessary for installation to proceed.

You must have the following partitions as a bare minimum:

• A / (root) partition

• A <swap> partition of type swap

Note
When defining a partition's type as swap, do not assign it a mount point. Anaconda automatically assigns the mount point for you.

9.3.6. Are You Seeing Python Errors?
During some upgrades or installations of Fedora, the installation program (also known as anaconda) may fail with a Python or traceback error. This error may occur after the selection of individual packages or while trying to save the upgrade log in the /tmp/directory. The error may look similar to:

```
Traceback (innermost last):
File "/var/tmp/anaconda-7.1//usr/lib/anaconda/iw/progress_gui.py", line 20, in run
rc = self.todo.doInstall ()
File "/var/tmp/anaconda-7.1//usr/lib/anaconda/todo.py", line 1468, in doInstall
self.fstab.savePartitions ()
File "fstab.py", line 221, in savePartitions
sys.exit(0)
```
This error occurs in some systems where links to /tmp/ are symbolic to other locations or have been changed since creation. These symbolic or changed links are invalid during the installation process, so the installation program cannot write information and fails.

If you experience such an error, first try to download any available updates for anaconda. Updates for anaconda and instructions for using them can be found at:

http://fedoraproject.org/wiki/Anaconda/Updates

You can also find and download errata for anaconda through your Red Hat Subscription. Log in to your account through the customer portal at https://access.redhat.com/login, click the Errata link at the top of the window, enter anaconda in the field marked Filter by Synopsis, and click go.

The anaconda website may also be a useful reference and can be found online at:

http://fedoraproject.org/wiki/Anaconda

You can also search for bug reports related to this problem. To search Red Hat's bug tracking system, go to:

http://bugzilla.redhat.com/bugzilla/

Finally, if you are still facing problems related to this error, register your product and contact our support team. To register your product, go to:

http://www.redhat.com/apps/activate/

9.4. Problems After Installation

9.4.1. Trouble With the Graphical GRUB Screen on an x86-based System?

If you are experiencing problems with GRUB, you may need to disable the graphical boot screen. To do this, become the root user and edit the /boot/grub/grub.conf file.

Within the grub.conf file, comment out the line which begins with splashimage by inserting the # character at the beginning of the line.

Press Enter to exit the editing mode.

Once the boot loader screen has returned, type b to boot the system.

Once you reboot, the grub.conf file is reread and any changes you have made take effect.
You may re-enable the graphical boot screen by uncommenting (or adding) the above line back into the `grub.conf` file.

### 9.4.2. Booting into a Graphical Environment

If you have installed the X Window System but are not seeing a graphical desktop environment once you log into your system, you can start the X Window System graphical interface using the command `startx`.

Once you enter this command and press `Enter`, the graphical desktop environment is displayed.

Note, however, that this is just a one-time fix and does not change the log in process for future log ins.

To set up your system so that you can log in at a graphical login screen, you must edit one file, `/etc/inittab`, by changing just one number in the runlevel section. When you are finished, reboot the computer. The next time you log in, you are presented with a graphical login prompt.

Open a shell prompt. If you are in your user account, become root by typing the `su` command.

Now, type `gedit /etc/inittab` to edit the file with `gedit`. The file `/etc/inittab` opens. Within the first screen, a section of the file which looks like the following appears:

```plaintext
# Default runlevel. The runlevels used are:
#   0 - halt (Do NOT set initdefault to this)
#   1 - Single user mode
#   2 - Multiuser, without NFS (The same as 3, if you do not have networking)
#   3 - Full multiuser mode
#   4 - unused
#   5 - X11
#   6 - reboot (Do NOT set initdefault to this)
#  id:3:initdefault:
```

To change from a console to a graphical login, you should change the number in the line `id:3:initdefault:` from a 3 to a 5.

**Warning**

Change only the number of the default runlevel from 3 to 5.

Your changed line should look like the following:

```
id:5:initdefault:
```

When you are satisfied with your change, save and exit the file using the `Ctrl+Q` keys. A window appears and asks if you would like to save the changes. Click `Save`.

The next time you log in after rebooting your system, you are presented with a graphical login prompt.

### 9.4.3. Problems with the X Window System (GUI)

If you are having trouble getting X (the X Window System) to start, you may not have installed it during your installation.

If you want X, you can either install the packages from the Fedora installation media or perform an upgrade.
If you elect to upgrade, select the X Window System packages, and choose GNOME, KDE, or both, during the upgrade package selection process.

Refer to Section 17.3, “Switching to a Graphical Login” for more detail on installing a desktop environment.

9.4.4. Problems with the X Server Crashing and Non-Root Users

If you are having trouble with the X server crashing when anyone logs in, you may have a full file system (or, a lack of available hard drive space).

To verify that this is the problem you are experiencing, run the following command:

```
df -h
```

The `df` command should help you diagnose which partition is full. For additional information about `df` and an explanation of the options available (such as the `-h` option used in this example), refer to the `df` man page by typing `man df` at a shell prompt.

A key indicator is 100% full or a percentage above 90% or 95% on a partition. The `/home/` and `/tmp/` partitions can sometimes fill up quickly with user files. You can make some room on that partition by removing old files. After you free up some disk space, try running X as the user that was unsuccessful before.

9.4.5. Problems When You Try to Log In

If you did not create a user account in the `firstboot` screens, switch to a console by pressing `Ctrl+Alt+F2`, log in as root and use the password you assigned to root.

If you cannot remember your root password, boot your system as `linux single`.

If you are using an x86-based system and GRUB is your installed boot loader, type `e` for edit when the GRUB boot screen has loaded. You are presented with a list of items in the configuration file for the boot label you have selected.

Choose the line that starts with `kernel` and type `e` to edit this boot entry.

At the end of the `kernel` line, add:

```
single
```

Press `Enter` to exit edit mode.

Once the boot loader screen has returned, type `b` to boot the system.

Once you have booted into single user mode and have access to the `#` prompt, you must type `passwd root`, which allows you to enter a new password for root. At this point you can type `shutdown -r now` to reboot the system with the new root password.

If you cannot remember your user account password, you must become root. To become root, type `su -` and enter your root password when prompted. Then, type `passwd <username>`. This allows you to enter a new password for the specified user account.

If the graphical login screen does not appear, check your hardware for compatibility issues. The Hardware Compatibility List can be found at:
Chapter 9. Troubleshooting Installation on an Intel or AMD System

9.4.6. Is Your RAM Not Being Recognized?
Sometimes, the kernel does not recognize all of your memory (RAM). You can check this with the cat /proc/meminfo command.

Verify that the displayed quantity is the same as the known amount of RAM in your system. If they are not equal, add the following line to the /boot/grub/grub.conf:

```
mem=xxM
```

Replace xx with the amount of RAM you have in megabytes.

In /boot/grub/grub.conf, the above example would look similar to the following:

```
# NOTICE: You have a /boot partition. This means that
# all kernel paths are relative to /boot/
default=0
timeout=30
splashimage=(hd0,0)/grub/splash.xpm.gz
title Fedora (2.6.27.19-170.2.35.fc10.i686)
root (hd0,1)
kernel /vmlinuz-2.6.27.19-170.2.35.fc10.i686 ro root=UUID=04a07c13-e6bf-6d5a-b207-082689545705 mem=1024M
initrd /initrd-2.6.27.19-170.2.35.fc10.i686.img
```

Once you reboot, the changes made to grub.conf are reflected on your system.

Once you have loaded the GRUB boot screen, type e for edit. You are presented with a list of items in the configuration file for the boot label you have selected.

Choose the line that starts with kernel and type e to edit this boot entry.

At the end of the kernel line, add

```
mem=xxM
```

where xx equals the amount of RAM in your system.

Press Enter to exit edit mode.

Once the boot loader screen has returned, type b to boot the system.

Itanium users must enter boot commands with elilo followed by the boot command.

Remember to replace xx with the amount of RAM in your system. Press Enter to boot.

9.4.7. Your Printer Does Not Work
If you are not sure how to set up your printer or are having trouble getting it to work properly, try using the Printer Configuration Tool.
Type the `system-config-printer` command at a shell prompt to launch the Printer Configuration Tool. If you are not root, it prompts you for the root password to continue.

9.4.8. Apache-based httpd service/Sendmail Hangs During Startup

If you are having trouble with the Apache-based `httpd` service or Sendmail hanging at startup, make sure the following line is in the `/etc/hosts` file:

```
127.0.0.1 localhost.localdomain localhost
```
Part III. Advanced installation options

This part of the *Fedora Installation Guide* covers more complex and uncommon methods of installing Fedora, including:

- boot options.
- installing without media.
- installing through VNC.
- using *kickstart* to automate the installation process.
Boot Options

The Fedora installation system includes a range of functions and options for administrators. To use boot options, enter `linux option` at the `boot:` prompt.

If you specify more than one option, separate each of the options by a single space. For example:

```
linux option1 option2 option3
```

### Anaconda Boot Options

The anaconda installer has many boot options, most are listed on the wiki [http://fedoraproject.org/wiki/Anaconda/Options](http://fedoraproject.org/wiki/Anaconda/Options).

### Kernel Boot Options

### Rescue Mode

The Fedora installation and rescue discs may either boot with `rescue mode`, or load the installation system. For more information on rescue discs and rescue mode, refer to Section 10.6.3, “Booting Your Computer with the Rescue Mode”.

### 10.1. Configuring the Installation System at the Boot Menu

You can use the boot menu to specify a number of settings for the installation system, including:

- language
- display resolution
- interface type
- Installation method
- network settings

### 10.1.1. Specifying the Language

To set the language for both the installation process and the final system, specify the ISO code for that language with the `lang` option. Use the `keymap` option to configure the correct keyboard layout.

For example, the ISO codes `el_GR` and `gr` identify the Greek language and the Greek keyboard layout:
10.1.2. Configuring the Interface
To use a specific display resolution, enter `resolution=setting` as a boot option. For example, to set the display resolution to 1024×768, enter:

```
linux resolution=1024x768
```

To run the installation process in **text** mode, enter:

```
linux text
```

To enable support for a serial console, enter `serial` as an additional option.

Use `display=ip:0` to allow remote display forwarding. In this command, `ip` should be replaced with the IP address of the system on which you want the display to appear.

On the system you want the display to appear on, you must execute the command `xhost +remotehostname`, where `remotehostname` is the name of the host from which you are running the original display. Using the command `xhost +remotehostname` limits access to the remote display terminal and does not allow access from anyone or any system not specifically authorized for remote access.

10.1.3. Updating anaconda
You can install Fedora with a newer version of the **anaconda** installation program than the one supplied on your installation media.

The boot option

```
linux updates
```

presents you with a prompt that asks you for a disk image containing **anaconda** updates. You do not need to specify this option if you are performing a network installation and have already placed the updates image contents in `rhupdates/` on the server.

To load the **anaconda** updates from a network location instead, use:

```
linux updates=
```

followed by the URL for the location where the updates are stored.

10.1.4. Specifying the Installation Method
Use the `askmethod` option to display additional menus that enable you to specify the installation method and network settings. You may also configure the installation method and network settings at the `boot:` prompt itself.
To specify the installation method from the `boot:` prompt, use the `repo` option. Refer to Table 10.1, “Installation methods” for the supported installation methods.

<table>
<thead>
<tr>
<th>Installation method</th>
<th>Option format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DVD drive</td>
<td><code>repo=cdrom:device</code></td>
</tr>
<tr>
<td>Hard Drive</td>
<td><code>repo=hd:device/path</code></td>
</tr>
<tr>
<td>HTTP Server</td>
<td><code>repo=http://host/path</code></td>
</tr>
<tr>
<td>FTP Server</td>
<td><code>repo=ftp://username:password@host/path</code></td>
</tr>
<tr>
<td>NFS Server</td>
<td><code>repo=nfs:server:/path</code></td>
</tr>
<tr>
<td>ISO images on an NFS Server</td>
<td><code>repo=nfsiso:server:/path</code></td>
</tr>
</tbody>
</table>

**10.2. Enabling Remote Access to the Installation System**

**Installing a VNC Client on Fedora**

Fedora includes the VNC client `vncviewer`. To obtain `vncviewer`, install the `tigervnc` package.

The installation system supports two methods of establishing a VNC connection. You may start the installation, and manually login to the graphical display with a VNC client on another system. Alternatively, you may configure the installation system to automatically connect to a VNC client on the network that is running in listening mode.

**10.2.1. Enabling Remote Access with VNC**

To enable remote graphical access to the installation system, enter two options at the prompt:

```
linux vnc vncpassword=qwerty
```

The `vnc` option enables the VNC service. The `vncpassword` option sets a password for remote access. The example shown above sets the password as `qwerty`. 
Chapter 10. Boot Options

VNC Passwords

The VNC password must be at least six characters long.

Specify the language, keyboard layout and network settings for the installation system with the screens that follow. You may then access the graphical interface through a VNC client. The installation system displays the correct connection setting for the VNC client:

Starting VNC...
The VNC server is now running.
Please connect to computer.mydomain.com:1 to begin the install...
Starting graphical installation...
Press <enter> for a shell

You may then login to the installation system with a VNC client. To run the vncviewer client on Fedora, choose Applications → Accessories → VNC Viewer, or type the command vncviewer in a terminal window. Enter the server and display number in the VNC Server dialog. For the example above, the VNC Server is computer.mydomain.com:1.

10.2.2. Connecting the Installation System to a VNC Listener

To have the installation system automatically connect to a VNC client, first start the client in listening mode. On Fedora systems, use the -listen option to run vncviewer as a listener. In a terminal window, enter the command:

vncviewer -listen

Firewall Reconfiguration Required

By default, vncviewer uses TCP port 5500 when in listening mode. To permit connections to this port from other systems, choose System → Administration → Firewall. Select Other ports, and Add. Enter 5500 in the Port(s) field, and specify tcp as the Protocol.

Once the listening client is active, start the installation system and set the VNC options at the boot: prompt. In addition to vnc and vncpassword options, use the vncconnect option to specify the name or IP address of the system that has the listening client. To specify the TCP port for the listener, add a colon and the port number to the name of the system.

For example, to connect to a VNC client on the system desktop.mydomain.com on the port 5500, enter the following at the boot: prompt:

```
linux vnc vncpassword=qwerty vncconnect=desktop.mydomain.com:5500
```

10.3. Logging to a Remote System During the Installation

By default, the installation process sends log messages to the console as they are generated. You may specify that these messages go to a remote system that runs a
10.3. Configuring a Log Server

Fedora uses rsyslog to provide a syslog service. The default configuration of rsyslog rejects messages from remote systems.

### Only Enable Remote Syslog Access on Secured Networks

The rsyslog configuration detailed below does not make use of any of the security measures available in rsyslog. Crackers may slow or crash systems that permit access to the logging service, by sending large quantities of false log messages. In addition, hostile users may intercept or falsify messages sent to the logging service over the network.

To configure a Fedora system to accept log messages from other systems on the network, edit the file /etc/rsyslog.conf. You must use root privileges to edit the file /etc/rsyslog.conf. Uncomment the following lines by removing the hash preceding them:

```bash
$ModLoad imudp.so
$UDPServerRun 514
```

Restart the rsyslog service to apply the change:

```bash
su -c '/sbin/service rsyslog restart'
```

Enter the root password when prompted.

### Firewall Reconfiguration Required

By default, the syslog service listens on UDP port 514. To permit connections to this port from other systems, choose System → Administration → Firewall. Select Other ports, and Add. Enter 514 in the Port(s) field, and specify udp as the Protocol.

10.4. Automating the Installation with Kickstart

You can allow an installation to run unattended by using Kickstart. A Kickstart file specifies settings for an installation. Once the installation system boots, it can read a Kickstart file and carry out the installation process without any further input from a user.
Every Installation Produces a Kickstart File

The Fedora installation process automatically writes a Kickstart file that contains the settings for the installed system. This file is always saved as /root/anaconda-ks.cfg. You may use this file to repeat the installation with identical settings, or modify copies to specify settings for other systems.

Important — Kickstart installations and Firstboot

Firstboot does not run after a system is installed from a Kickstart file unless a desktop and the X Window System were included in the installation and graphical login was enabled. Either specify a user with the user option in the Kickstart file before installing additional systems from it (refer to Section 14.4, “Kickstart Options” for details) or log into the installed system with a virtual console as root and add users with the adduser command.

Fedora includes a graphical application to create and modify Kickstart files by selecting the options that you require. Use the package system-config-kickstart to install this utility. To load the Fedora Kickstart editor, choose Applications → System Tools → Kickstart.

Kickstart files list installation settings in plain text, with one option per line. This format lets you modify your Kickstart files with any text editor, and write scripts or applications that generate custom Kickstart files for your systems.

To automate the installation process with a Kickstart file, use the ks option to specify the name and location of the file:

```
linux ks=location/kickstart-file.cfg
```

You may use Kickstart files that are held on either removable storage, a hard drive, or a network server. Refer to Table 10.2, “Kickstart sources” for the supported Kickstart sources.

Table 10.2. Kickstart sources

<table>
<thead>
<tr>
<th>Kickstart source</th>
<th>Option format</th>
</tr>
</thead>
<tbody>
<tr>
<td>DVD drive</td>
<td>ks=cdrom:/directory/ks.cfg</td>
</tr>
<tr>
<td>Hard Drive</td>
<td>ks=hd:/device/directory/ks.cfg</td>
</tr>
<tr>
<td>Other Device</td>
<td>ks=file:/device/directory/ks.cfg</td>
</tr>
<tr>
<td>HTTP Server</td>
<td>ks=<a href="http://server.mydomain.com/directory/ks.cfg">http://server.mydomain.com/directory/ks.cfg</a></td>
</tr>
<tr>
<td>FTP Server</td>
<td>ks=ftp://server.mydomain.com/directory/ks.cfg</td>
</tr>
<tr>
<td>NFS Server</td>
<td>ks=nfs://server.mydomain.com:/directory/ks.cfg</td>
</tr>
</tbody>
</table>

To obtain a Kickstart file from a script or application on a Web server, specify the URL of the application with the ks= option. If you add the option kssendmac, the request also sends HTTP headers to the Web application. Your application can use these headers to identify the computer. This line sends a request with headers to the application http://server.mydomain.com/kickstart.cgi:
10.5. Enhancing Hardware Support

By default, Fedora attempts to automatically detect and configure support for all of the components of your computer. Fedora supports the majority of hardware in common use with the software drivers that are included with the operating system. To support other devices you may supply additional drivers during the installation process, or at a later time.

10.5.1. Overriding Automatic Hardware Detection

For some models of device automatic hardware configuration may fail, or cause instability. In these cases, you may need to disable automatic configuration for that type of device, and take additional steps to manually configure the device after the installation process is complete.

Check the Release Notes

Refer to the Release Notes for information on known issues with specific devices.

To override the automatic hardware detection, use one or more of the following options:

Table 10.3. Hardware Options

<table>
<thead>
<tr>

Chapter 10. Boot Options

**Additional Screen**

The *isa* option causes the system to display an additional text screen at the beginning of the installation process. Use this screen to configure the ISA devices on your computer.

**Important**

Other kernel boot options have no particular meaning for *anaconda* and do not affect the installation process. However, if you use these options to boot the installation system, *anaconda* will preserve them in the bootloader configuration.

10.6. Using the Maintenance Boot Modes

10.6.1. Loading the Memory (RAM) Testing Mode

Faults in memory modules may cause your system to freeze or crash unpredictably. In some cases, memory faults may only cause errors with particular combinations of software. For this reason, you should test the memory of a computer before you install Fedora for the first time, even if it has previously run other operating systems.

Fedora includes the *Memtest86+* memory testing application. To boot your computer in memory testing mode, choose *Memory test* at the boot menu. The first test starts immediately. By default, *Memtest86+* carries out a total of ten tests.

In most cases, a single successful pass with *Memtest86+* is sufficient to verify that your RAM is in good condition. In some rare circumstances, however, errors that went undetected on the first pass might appear on subsequent passes. To perform a thorough test of the RAM on an important system, leave *Memtest86+* running overnight or for a few days.

To halt the tests and reboot your computer, enter Esc at any time.

10.6.2. Verifying boot media

You can test the integrity of an ISO-based installation source before using it to install Fedora. These sources include DVD, and ISO images stored on a hard drive or NFS server. Verifying that the ISO images are intact before you attempt an installation helps to avoid problems that are often encountered during installation.

Fedora offers you two ways to test installation ISOS:

- select OK at the prompt to test the media before installation when booting from the Fedora DVD
- boot Fedora with the option *mediacheck* option.

10.6.3. Booting Your Computer with the Rescue Mode

You may boot a command-line Linux system from either a
rescue disc or an installation disc, without installing Fedora on the computer. This enables you to use the utilities and functions of a running Linux system to modify or repair systems that are already installed on your computer.

The rescue disc starts the rescue mode system by default. To load the rescue system with the installation disc, choose **Rescue installed system** from the boot menu.

Specify the language, keyboard layout and network settings for the rescue system with the screens that follow. The final setup screen configures access to the existing system on your computer.

By default, rescue mode attaches an existing operating system to the rescue system under the directory `/mnt/sysimage/`.

### 10.6.4. Upgrading your computer

A previous boot option, **upgrade**, has been superceded by a stage in the installation process where the installation program prompts you to upgrade or reinstall earlier versions of Fedora that it detects on your system.

However, the installation program may not correctly detect a previous version of Fedora if the contents of the `/etc/redhat-release` file have changed. The boot option **upgradedany** relaxes the test that the installation program performs and allows you to upgrade a Fedora installation that the installation program has not correctly identified.
Chapter 11.

Installing Without Media

Linux Required

This procedure assumes you are already using Fedora or another relatively modern Linux distribution, and the GRUB boot loader. It also assumes you are a somewhat experienced Linux user.

This section discusses how to install Fedora on your system without making any additional physical media. Instead, you can use your existing GRUB boot loader to start the installation program.

11.1. Retrieving Boot Files

To perform an installation without media or a PXE server, your system must have two files stored locally, a kernel and an initial RAM disk.

Copy the vmlinuz and initrd.img files from a Fedora DVD (or DVD image) to the /boot/ directory, renaming them to vmlinuz-install and initrd.img-install. You must have root privileges to write files into the /boot/ directory.

11.2. Editing the GRUB Configuration

The GRUB boot loader uses the configuration file /boot/grub/grub.conf. To configure GRUB to boot from the new files, add a boot stanza to /boot/grub/grub.conf that refers to them.

A minimal boot stanza looks like the following listing:

```
title Installation
   root (hd0,0)
   kernel /vmlinuz-install
   initrd /initrd.img-install
```

You may wish to add options to the end of the kernel line of the boot stanza. These options set preliminary options in Anaconda which the user normally sets interactively. For a list of available installer boot options, refer to Chapter 10, Boot Options.

The following options are generally useful for medialess installations:

- ip=
- repo=
- lang=
- keymap=
- ksdevice= (if installation requires an interface other than eth0)
- vnc and vncpassword= for a remote installation

When you are finished, change the default option in /boot/grub/grub.conf to point to the new first stanza you added:
11.3. Booting to Installation

Reboot the system. GRUB boots the installation kernel and RAM disk, including any options you set. You may now refer to the appropriate chapter in this guide for the next step. If you chose to install remotely using VNC, refer to Section 10.2, “Enabling Remote Access to the Installation System” for assistance in connecting to the remote system.
Chapter 12.

Setting Up an Installation Server

Experience Required

This appendix is intended for users with previous Linux experience. If you are a new user, you may want to install using minimal boot media or the distribution DVD instead.

Warning

The instructions in this appendix configure an automated install server. The default configuration includes destruction of all existing data on all disks for hosts that install using this method. This is often different from other network install server configurations which may provide for an interactive installation experience.

Fedora allows for installation over a network using the NFS, FTP, or HTTP protocols. A network installation can be started from a boot CD-ROM, a bootable flash memory drive, or by using the askmethod boot option with the Fedora DVD. Alternatively, if the system to be installed contains a network interface card (NIC) with Pre-Execution Environment (PXE) support, it can be configured to boot from files on another networked system rather than local media such as a DVD.

For a PXE network installation, the client's NIC with PXE support sends out a broadcast request for DHCP information. The DHCP server provides the client with an IP address, other network information such as name server, the IP address or hostname of the tftp server (which provides the files necessary to start the installation program), and the location of the files on the tftp server. This is possible because of PXELINUX, which is part of the syslinux package.

In the past, administrators needed to perform a great deal of manual configuration to produce an installation server. However, if you have a server running Fedora or a similar operating system on your local network, you can use cobbler to perform these tasks. To configure a PXE server manually, see Section 12.5, “Manually configure a PXE server”.

To perform the tasks in this section, switch to the root account with the command su -. As an alternative, you can run a command with the -c option, using the form su -c 'command'.

12.1. Setting Up cobbler

To install cobbler use the following command:

```bash
yum -y install cobbler
```

The cobbler command can check its own settings for validity and report the results. Run the following command to check the settings:

```bash
cobbler check
```

Change the settings in the /etc/cobbler/settings file to reflect the IP address information for the server. You must change at least the server and next_server options, although these options may point to the same IP address.
Chapter 12. Setting Up an Installation Server

If you are not already running a DHCP server, you should also change the `manage_dhcp` option to `1`. If you are running a DHCP server, configure it according to the instructions found in the `syslinux` package documentation. For more information, refer to your local files `/usr/share/doc/syslinux-version/syslinux.doc` and `/usr/share/doc/syslinux-version/pxelinux.doc`.

12.2. Setting Up the Distribution
To set up a distribution from a full Fedora DVD or ISO image, use this procedure.

**Network Locations**

To create a local mirror from an existing network source, skip this section and refer instead to Section 12.3, ”Mirroring a Network Location”.

1. If you are using a DVD disc or ISO image, Create a directory mount point:

   ```
   mkdir /mnt/dvd
   ```

   To mount a physical DVD disc, use the following command:

   ```
   mount -o context=system_u:object_r:httpd_sys_content_t:s0 /dev/dvd /mnt/dvd
   ```

   To mount a DVD ISO image, use the following command:

   ```
   mount -ro loop,context=system_u:object_r:httpd_sys_content_t:s0 /path/to/image.iso /mnt/dvd
   ```

2. To support NFS installation, create a file `/etc/exports` and add the following line to it:

   ```
   /mnt/dvd *(ro,async)
   ```

   Start the NFS server using the following commands:

   ```
   /sbin/service rpcbind start /sbin/service nfs start
   ```

3. To support HTTP installation, use `yum` to install the Apache web server if it is not already installed:

   ```
   yum -y install httpd
   ```

   Make a link to the mounted disc in the Apache public content area:

   ```
   ln -s /mnt/dvd /var/www/html/distro
   ```

12.3. Mirroring a Network Location
If you do not have discs or ISO images for a distribution, you can use `cobbler` to create an installation server. The `cobbler` command can fetch the distribution over the network as part of the import process.
Locate the distribution on the network. The location may be on the local network or reached at a remote site via FTP, HTTP, or rsync protocols.

12.4. Importing the Distribution

To offer a distribution through more than one installation method, perform additional `cobbler import` tasks using a different name for each method. For best results, use the installation method as part of the name, so it appears in the client's boot menu.

1. To import the DVD disc or ISO distribution into `cobbler`, run this command:

   ```
cobbler import --path=/mnt/dvd --name=distro_name
   ```

   For `distro_name`, substitute a meaningful name for the distribution.

   To import a local or remote network distribution into `cobbler`, run this command. Replace `network_URI` with the URI you found in Section 12.3, “Mirroring a Network Location”, and `distro_name` as above:

   ```
cobbler import --path=network_URI --name=distro_name
   ```

   **Importing a Source**

   When `cobbler` imports a distribution with the commands above, it copies all the files to the server's local storage, which may take some time.

   If you do not want to make local copies of the distribution because clients can already reach its location, use the `--available-as` option.

   ```
cobbler import --path=/mnt/dvd --name=distro_name --available-as=network_URI
   cobbler import --path=network_URI --name=distro_name --available-as=network_URI
   ```

   For `network_URI`, substitute the appropriate network location of the distribution. This URI indicates how the server makes the distribution available to its clients. The examples above assume that your `cobbler` server reaches the mirror location at the same URI as the clients. If not, substitute an appropriate URI for the `--path` option. The following examples are URI locations that work if you have been following the procedures in this section, and your server's IP address is 192.168.1.1:

   • `nfs://192.168.1.1:/mnt/dvd`
   • `http://192.168.1.1:/distro`

   If necessary, replace 192.168.1.1 with the IP address for your `cobbler` server.

2. Run the command `cobbler sync` to apply the changes. To check that your `cobbler` server is listening on the correct ports, use the `netstat -lp` command.

12.5. Manually configure a PXE server

The following steps must be performed to prepare for a PXE installation:

1. Configure the network (NFS, FTP, HTTP) server to export the installation tree.
2. Configure the files on the tftp server necessary for PXE booting.
3. Configure which hosts are allowed to boot from the PXE configuration.
4. Start the tftp service.
5. Configure DHCP.
6. Boot the client, and start the installation.

12.5.1. Setting up the Network Server

First, configure an NFS, FTP, or HTTP server to export the entire installation tree for the version and variant of Fedora to be installed. Refer to Section 5.1, “Preparing for a Network Installation” for detailed instructions.

12.5.2. PXE Boot Configuration

The next step is to copy the files necessary to start the installation to the tftp server so they can be found when the client requests them. The tftp server is usually the same server as the network server exporting the installation tree.

To copy these files, run the Network Booting Tool on the NFS, FTP, or HTTP server. A separate PXE server is not necessary.

12.5.3. Adding PXE Hosts

After configuring the network server, the interface as shown in Figure 12.1, “Add Hosts” is displayed.
The next step is to configure which hosts are allowed to connect to the PXE boot server.

To add hosts, click the **New** button.

- **Hostname or IP Address/Subnet** — The IP address, fully qualified hostname, or a subnet of systems that should be allowed to connect to the PXE server for installations.

- **Operating System** — The operating system identifier to install on this client. The list is populated from the network install instances created from the **Network Installation Dialog**.

- **Serial Console** — This option allows use of a serial console.

- **Kickstart File** — The location of a kickstart file to use, such as `http://server.example.com/kickstart/ks.cfg`. This file can be created with the **Kickstart Configurator**. Refer to *Chapter 15, Kickstart Configurator* for details.
Ignore the **Snapshot name** and **Ethernet** options. They are only used for diskless environments.

### 12.5.4. TFTP

#### 12.5.4.1. Starting the tftp Server

On the DHCP server, verify that the `tftp-server` package is installed with the command `rpm -q tftp-server`.

`tftp` is an xinetd-based service; start it with the following commands:

```
/sbin/chkconfig --level 345 xinetd on
/sbin/chkconfig --level 345 tftp on
```

These commands configure the `tftp` and `xinetd` services to immediately turn on and also configure them to start at boot time in runlevels 3, 4, and 5.

### 12.5.5. Configuring the DHCP Server

If a DHCP server does not already exist on the network, configure one. Refer to the Fedora Deployment Guide for details. Make sure the configuration file contains the following so that PXE booting is enabled for systems which support it:

```
allow booting; allow bootp; class "pxeclients" {
    match if substring(option vendor-class-identifier, 0, 9) = "PXEClient";
    next-server <server-ip>;
    filename "linux-install/pxelinux.0";
}
```

where the `next-server <server-ip>` should be replaced with the IP address of the `tftp` server.

### 12.5.6. Adding a Custom Boot Message

Optionally, modify `/tftpboot/linux-install/msgs/boot.msg` to use a custom boot message.

### 12.5.7. Performing the PXE Installation

For instructions on how to configure the network interface card with PXE support to boot from the network, consult the documentation for the NIC. It varies slightly per card.

If your NIC does not support PXE booting, you can still PXE boot your system by using the gPXE bootloader. Red Hat does not distribute gPXE — refer to the Etherboot Project website at `http://etherboot.org/wiki/start` for more information.

After the system boots the installation program, refer to the *Chapter 8, Installing using anaconda*. 

---

140
Installing Through VNC

The Red Hat Enterprise Linux and Fedora installer (anaconda) offers you two interactive modes of operation. The original mode is a text-based interface. The newer mode uses GTK+ and runs in the X Window environment. This chapter explains how you can use the graphical installation mode in environments where the system lacks a proper display and input devices typically associated with a workstation. This scenario is typical of systems in datacenters, which are often installed in a rack environment and do not have a display, keyboard, or mouse. Additionally, a lot of these systems even lack the ability to connect a graphical display. Given that enterprise hardware rarely needs that ability at the physical system, this hardware configuration is acceptable.

Even in these environments, however, the graphical installer remains the recommended method of installation. The text mode environment lacks a lot of capabilities found in the graphical mode. Many users still feel that the text mode interface provides them with additional power or configuration ability not found in the graphical version. The opposite is true. Much less development effort is put in to the text-mode environment and specific things (for example, LVM configuration, partition layout, package selection, and bootloader configuration) are deliberately left out of the text mode environment. The reasons for this are:

- Less screen real estate for creating user interfaces similar to those found in the graphical mode.
- Difficult internationalization support.
- Desire to maintain a single interactive installation code path.

Anaconda therefore includes a Virtual Network Computing (VNC) mode that allows the graphical mode of the installer to run locally, but display on a system connected to the network. Installing in VNC mode provides you with the full range of installation options, even in situations where the system lacks a display or input devices.

13.1. VNC Viewer

Performing a VNC installation requires a VNC viewer running on your workstation or other terminal computer. Locations where you might want a VNC viewer installed:

- Your workstation
- Laptop on a datacenter crash cart

VNC is open source software licensed under the GNU General Public License. Versions exist for Linux, Windows, and MacOS X. Here are some recommended VNC viewers:

- VNC clients are available in the repositories of most Linux distributions. Use your package manager to search for a client for your chosen distribution. For example, on Fedora, install the tigervnc package:

  
  # yum install tigervnc

- TightVNC is available for Windows at http://www.tightvnc.com/

- MacOS X includes built-in VNC support as of version 10.5. In the Finder, click the Go menu and choose Connect to Server. In the server address field, you can type vnc://SERVER:DISPLAY, where SERVER is the IP address or DNS host name of the VNC server you wish to connect to and DISPLAY is the VNC display number (usually 1), and click Connect.

Once you have verified you have a VNC viewer available, it's time to start the installation.
13.2. VNC Modes in Anaconda

Anaconda offers two modes for VNC installation. The mode you select will depend on the network configuration in your environment.

13.2.1. Direct Mode

Direct mode VNC in anaconda is when the client initiates a connection to the VNC server running in anaconda. Anaconda will tell you when to initiate this connection in the VNC viewer. Direct mode can be activated by either of the following commands:

- Specify `vnc` as a boot argument.
- Specify the `vnc` command in the kickstart file used for installation.

When you activate VNC mode, anaconda will complete the first stage of the installer and then start VNC to run the graphical installer. The installer will display a message on the console in the following format:

```
Running anaconda VERSION, the PRODUCT system installer - please wait...
```

Anaconda will also tell you the IP address and display number to use in your VNC viewer. At this point, you need to start the VNC viewer and connect to the target system to continue the installation. The VNC viewer will present anaconda to you in graphical mode.

There are some disadvantages to direct mode, including:

- Requires visual access to the system console to see the IP address and port to connect the VNC viewer to.
- Requires interactive access to the system console to complete the first stage of the installer.

If either of these disadvantages would prevent you from using direct mode VNC in anaconda, then connect mode is probably more suited to your environment.

13.2.2. Connect Mode

Certain firewall configurations or instances where the target system is configured to obtain a dynamic IP address may cause trouble with the direct VNC mode in anaconda. In addition, if you lack a console on the target system to see the message that tells you the IP address to connect to, then you will not be able to continue the installation.

The VNC connect mode changes how VNC is started. Rather than anaconda starting up and waiting for you to connect, the VNC connect mode allows anaconda to automatically connect to your view. You won't need to know the IP address of the target system in this case.

To activate the VNC connect mode, pass the `vncconnect` boot parameter:

```
boot: linux vncconnect=HOST
```

Replace HOST with your VNC viewer’s IP address or DNS host name. Before starting the installation process on the target system, start up your VNC viewer and have it wait for an incoming connection.

Start the installation and when your VNC viewer displays the graphical installer, you are ready to go.
Installation Using VNC

13.3. Installation Using VNC

Now that you have installed a VNC viewer application and selected a VNC mode for use in anaconda, you are ready to begin the installation.

13.3.1. Installation Example

The easiest way to perform an installation using VNC is to connect another computer directly to the network port on the target system. The laptop on a datacenter crash cart usually fills this role. If you are performing your installation this way, make sure you follow these steps:

1. Connect the laptop or other workstation to the target system using a crossover cable. If you are using regular patch cables, make sure you connect the two systems using a small hub or switch. Most recent Ethernet interfaces will automatically detect if they need to be crossover or not, so it may be possible to connect the two systems directly using a regular patch cable.

2. Configure the VNC viewer system to use a RFC 1918 address with no gateway. This private network connection will only be used for the purpose of installation. Configure the VNC viewer system to be 192.168.100.1/24. If that address is in use, just pick something else in the RFC 1918 address space that is available to you.

3. Start the installation on the target system.
   a. Booting the installation DVD.
      
      If booting the installation DVD, make sure `vnc` is passed as a boot parameter. To add the `vnc` parameter, you will need a console attached to the target system that allows you to interact with the boot process. Enter the following at the prompt:

      ```
      boot: linux vnc
      ```

   b. Boot over the network.
      
      If the target system is configured with a static IP address, add the `vnc` command to the kickstart file. If the target system is using DHCP, add `vncconnect=HOST` to the boot arguments for the target system. HOST is the IP address or DNS host name of the VNC viewer system. Enter the following at the prompt:

      ```
      boot: linux vncconnect=HOST
      ```

4. When prompted for the network configuration on the target system, assign it an available RFC 1918 address in the same network you used for the VNC viewer system. For example, 192.168.100.2/24.

   **Note**

   This IP address is only used during installation. You will have an opportunity to configure the final network settings, if any, later in the installer.

5. Once the installer indicates it is starting anaconda, you will be instructed to connect to the system using the VNC viewer. Connect to the viewer and follow the graphical installation mode instructions found in the product documentation.
13.3.2. Kickstart Considerations

If your target system will be booting over the network, VNC is still available. Just add the `vnc` command to the kickstart file for the system. You will be able to connect to the target system using your VNC viewer and monitor the installation progress. The address to use is the one the system is configured with via the kickstart file.

If you are using DHCP for the target system, the reverse `vncconnect` method may work better for you. Rather than adding the `vnc` boot parameter to the kickstart file, add the `vncconnect=HOST` parameter to the list of boot arguments for the target system. For HOST, put the IP address or DNS host name of the VNC viewer system. See the next section for more details on using the vncconnect mode.

13.3.3. Firewall Considerations

If you are performing the installation where the VNC viewer system is a workstation on a different subnet from the target system, you may run into network routing problems. VNC works fine so long as your viewer system has a route to the target system and ports 5900 and 5901 are open. If your environment has a firewall, make sure ports 5900 and 5901 are open between your workstation and the target system.

In addition to passing the `vnc` boot parameter, you may also want to pass the `vncpassword` parameter in these scenarios. While the password is sent in plain text over the network, it does provide an extra step before a viewer can connect to a system. Once the viewer connects to the target system over VNC, no other connections are permitted. These limitations are usually sufficient for installation purposes.

**Important**

Be sure to use a temporary password for the `vncpassword` option. It should not be a password you use on any systems, especially a real root password.

If you continue to have trouble, consider using the `vncconnect` parameter. In this mode of operation, you start the viewer on your system first telling it to listen for an incoming connection. Pass `vncconnect=HOST` at the boot prompt and the installer will attempt to connect to the specified HOST (either a hostname or IP address).

13.4. References

- Anaconda boot options: [http://fedoraproject.org/wiki/Anaconda/Options](http://fedoraproject.org/wiki/Anaconda/Options)

Chapter 14.

Kickstart Installations

14.1. What are Kickstart Installations?

Many system administrators would prefer to use an automated installation method to install Fedora on their machines. To answer this need, Red Hat created the kickstart installation method. Using kickstart, a system administrator can create a single file containing the answers to all the questions that would normally be asked during a typical installation.

Kickstart files can be kept on a single server system and read by individual computers during the installation. This installation method can support the use of a single kickstart file to install Fedora on multiple machines, making it ideal for network and system administrators.

Kickstart provides a way for users to automate a Fedora installation.

All kickstart scriptlets and the log files of their execution are stored in the /tmp directory to assist with debugging installation failures.

14.2. How Do You Perform a Kickstart Installation?

Kickstart installations can be performed using a local DVD, a local hard drive, or via NFS, FTP, or HTTP.

To use kickstart, you must:

1. Create a kickstart file.
2. Create a boot media with the kickstart file or make the kickstart file available on the network.
3. Make the installation tree available.
4. Start the kickstart installation.

This chapter explains these steps in detail.

14.3. Creating the Kickstart File

The kickstart file is a simple text file, containing a list of items, each identified by a keyword. You can create it by using the Kickstart Configurator application, or writing it from scratch. The Fedora installation program also creates a sample kickstart file based on the options that you selected during installation. It is written to the file /root/anaconda-ks.cfg. You should be able to edit it with any text editor or word processor that can save files as ASCII text.

First, be aware of the following issues when you are creating your kickstart file:

- Sections must be specified in order. Items within the sections do not have to be in a specific order unless otherwise specified. The section order is:
  - Command section — Refer to Section 14.4, “Kickstart Options” for a list of kickstart options. You must include the required options.
  - The %packages section — Refer to Section 14.5, “Package Selection” for details.
  - The %pre and %post sections — These two sections can be in any order and are not required. Refer to Section 14.6, “Pre-installation Script” and Section 14.7, “Post-installation Script” for details.
Chapter 14. Kickstart Installations

• Items that are not required can be omitted.

• Omitting any required item results in the installation program prompting the user for an answer to the related item, just as the user would be prompted during a typical installation. Once the answer is given, the installation continues unattended (unless it finds another missing item).

• Lines starting with a pound (also known as hash) sign (#) are treated as comments and are ignored.

• For kickstart upgrades, the following items are required:
  • Language
  • Installation method
  • Device specification (if device is needed to perform the installation)
  • Keyboard setup
  • The upgrade keyword
  • Boot loader configuration

If any other items are specified for an upgrade, those items are ignored (note that this includes package selection).

14.4. Kickstart Options
The following options can be placed in a kickstart file. If you prefer to use a graphical interface for creating your kickstart file, use the Kickstart Configurator application. Refer to Chapter 15, Kickstart Configurator for details.

Note
If the option is followed by an equals mark (=), a value must be specified after it. In the example commands, options in brackets ([]) are optional arguments for the command.

autoboot (optional)
Automatically create partitions — 1 GB or more root (/) partition, a swap partition, and an appropriate boot partition for the architecture. One or more of the default partition sizes can be redefined with the part directive.

• --encrypted — Should all devices with support be encrypted by default? This is equivalent to checking the Encrypt checkbox on the initial partitioning screen.

• --passphrase= — Provide a default system-wide passphrase for all encrypted devices.

• --escrowcert=URL_of_X.509_certificate — Store data encryption keys of all encrypted volumes as files in / (root), encrypted using the X.509 certificate from the URL specified with URL_of_X.509_certificate. The keys are stored as a separate file for each encrypted volume. This option is only meaningful if --encrypted is specified.

• --backuppassphrase= — Add a randomly-generated passphrase to each encrypted volume. Store these passphrases in separate files in / (root), encrypted using the X.509 certificate specified with --escrowcert. This option is only meaningful if --escrowcert is specified.
ignoredisk (optional)
Causes the installer to ignore the specified disks. This is useful if you use autopartition and want to be sure that some disks are ignored. For example, without ignoredisk, attempting to deploy on a SAN-cluster the kickstart would fail, as the installer detects passive paths to the SAN that return no partition table.

The ignoredisk option is also useful if you have multiple paths to your disks.

The syntax is:

```
ignoredisk --drives=drive1,drive2,...
```

where driveN is one of sda, sdb,..., hda,... etc.

- **--only-use** — specifies a list of disks for the installer to use. All other disks are ignored. For example, to use disk sda during installation and ignore all other disks:

```
ignoredisk --only-use=sda
```

autostep (optional)
Similar to interactive except it goes to the next screen for you. It is used mostly for debugging.

- **--autoscreenshot** — Take a screenshot at every step during installation and copy the images over to `/root/anaconda-screenshots` after installation is complete. This is most useful for documentation.

auth or authconfig (required)
Sets up the authentication options for the system. It is similar to the authconfig command, which can be run after the install. By default, passwords are normally encrypted and are not shadowed.

- **--enablemd5** — Use md5 encryption for user passwords.

- **--enablenis** — Turns on NIS support. By default, **--enablenis** uses whatever domain it finds on the network. A domain should almost always be set by hand with the **--nisdomain** option.

- **--nisdomain** — NIS domain name to use for NIS services.

- **--nisserver** — Server to use for NIS services (broadcasts by default).

- **--useshadow** or **--enableshadow** — Use shadow passwords.

- **--enabledldap** — Turns on LDAP support in `/etc/nsswitch.conf`, allowing your system to retrieve information about users (UIDs, home directories, shells, etc.) from an LDAP directory. To use this option, you must install the nss_ldap package. You must also specify a server and a base DN (distinguished name) with **--ldapserver** and **--ldapbasedn**.

- **--enabledldapauth** — Use LDAP as an authentication method. This enables the pam_ldap module for authentication and changing passwords, using an LDAP directory. To use this option, you must have the nss_ldap package installed. You must also specify a server and a base DN with **--ldapserver** and **--ldapbasedn**.

- **--ldapserver** — If you specified either **--enabledldap** or **--enabledldapauth**, use this option to specify the name of the LDAP server to use. This option is set in the `/etc/ldap.conf` file.
• **--ldapbasedn=** — If you specified either **--enableldap** or **--enableldapauth**, use this option to specify the DN in your LDAP directory tree under which user information is stored. This option is set in the `/etc/ldap.conf` file.

• **--enableldaptls** — Use TLS (Transport Layer Security) lookups. This option allows LDAP to send encrypted usernames and passwords to an LDAP server before authentication.

• **--enablekrb5** — Use Kerberos 5 for authenticating users. Kerberos itself does not know about home directories, UIDs, or shells. If you enable Kerberos, you must make users’ accounts known to this workstation by enabling LDAP, NIS, or Hesiod or by using the `/usr/sbin/useradd` command. If you use this option, you must have the `pam_krb5` package installed.

• **--krb5realm=** — The Kerberos 5 realm to which your workstation belongs.

• **--krb5kdc=** — The KDC (or KDCs) that serve requests for the realm. If you have multiple KDCs in your realm, separate their names with commas (,).

• **--krb5adminserver=** — The KDC in your realm that is also running kadmind. This server handles password changing and other administrative requests. This server must be run on the master KDC if you have more than one KDC.

• **--enablehesiod** — Enable Hesiod support for looking up user home directories, UIDs, and shells. More information on setting up and using Hesiod on your network is in `/usr/share/doc/glibc-2.x.x/README.hesiod`, which is included in the `glibc` package. Hesiod is an extension of DNS that uses DNS records to store information about users, groups, and various other items.

• **--hesiodlhs** — The Hesiod LHS ("left-hand side") option, set in `/etc/hesiod.conf`. This option is used by the Hesiod library to determine the name to search DNS for when looking up information, similar to LDAP’s use of a base DN.

• **--hesiodrhs** — The Hesiod RHS ("right-hand side") option, set in `/etc/hesiod.conf`. This option is used by the Hesiod library to determine the name to search DNS for when looking up information, similar to LDAP’s use of a base DN.

**Note**

To look up user information for "jim", the Hesiod library looks up `jim.passwd<LHS><RHS>`, which should resolve to a TXT record that looks like what his passwd entry would look like (`jim:*:501:501:Jungle Jim:/home/jim:/bin/bash`). For groups, the situation is identical, except `jim.group<LHS><RHS>` would be used.

Looking up users and groups by number is handled by making "501.uid" a CNAME for "jim.passwd", and "501.gid" a CNAME for "jim.group". Note that the library does not place a period . in front of the LHS and RHS values when performing a search. Therefore the LHS and RHS values need to have a period placed in front of them in order if they require this.

• **--enablesmbauth** — Enables authentication of users against an SMB server (typically a Samba or Windows server). SMB authentication support does not know about home directories, UIDs, or shells. If you enable SMB, you must make users’ accounts known to the workstation by enabling LDAP, NIS, or Hesiod or by using the `/usr/sbin/useradd` command to make their accounts known to the workstation. To use this option, you must have the `pam_smb` package installed.
•  **--smbservers=** — The name of the server(s) to use for SMB authentication. To specify more than one server, separate the names with commas (,).

•  **--smbworkgroup=** — The name of the workgroup for the SMB servers.

•  **--enablecache** — Enables the *nscd* service. The *nscd* service caches information about users, groups, and various other types of information. Caching is especially helpful if you choose to distribute information about users and groups over your network using NIS, LDAP, or hesiod.

**bootloader** (required)

Specifies how the boot loader should be installed. This option is required for both installations and upgrades.

![](Important)

If you select text mode for a kickstart installation, make sure that you specify choices for the partitioning, bootloader, and package selection options. These steps are automated in text mode, and *anaconda* cannot prompt you for missing information. If you do not provide choices for these options, *anaconda* will stop the installation process.

•  **--append=** — Specifies kernel parameters. To specify multiple parameters, separate them with spaces. For example:

   ```
   bootloader --location=mbr --append="hdd=ide-scsi ide=nodma"
   ```

•  **--driveorder** — Specify which drive is first in the BIOS boot order. For example:

   ```
   bootloader --driveorder=sda,hda
   ```

•  **--location=** — Specifies where the boot record is written. Valid values are the following: *mbr* (the default), *partition* (installs the boot loader on the first sector of the partition containing the kernel), or *none* (do not install the boot loader).

•  **--password=** — If using GRUB, sets the GRUB boot loader password to the one specified with this option. This should be used to restrict access to the GRUB shell, where arbitrary kernel options can be passed.

•  **--md5pass=** — If using GRUB, similar to **--password=** except the password should already be encrypted.

•  **--upgrade** — Upgrade the existing boot loader configuration, preserving the old entries. This option is only available for upgrades.

**clearpart** (optional)

Removes partitions from the system, prior to creation of new partitions. By default, no partitions are removed.
Chapter 14. Kickstart Installations

**Note**

If the `clearpart` command is used, then the `--onpart` command cannot be used on a logical partition.

- **--all** — Erases all partitions from the system.
- **--drives=** — Specifies which drives to clear partitions from. For example, the following clears all the partitions on the first two drives on the primary IDE controller:

  ```bash
clearpart --drives=hda,hdb --all
  ```

- **--initlabel** — Initializes the disk label to the default for your architecture (for example `mdsos` for x86). It is useful so that the installation program does not ask if it should initialize the disk label if installing to a brand new hard drive.
- **--linux** — Erases all Linux partitions.
- **--none** (default) — Do not remove any partitions.

**cmdline** (optional)

Perform the installation in a completely non-interactive command line mode. Any prompt for interaction halts the install.

**device** (optional)

On most PCI systems, the installation program autoprobes for Ethernet and SCSI cards properly. On older systems and some PCI systems, however, kickstart needs a hint to find the proper devices. The `device` command, which tells the installation program to install extra modules, is in this format:

```bash
device <moduleName> --opts=<options>
```

- `<moduleName>` — Replace with the name of the kernel module which should be installed.
- **--opts=** — Mount options to use for mounting the NFS export. Any options that can be specified in `/etc/fstab` for an NFS mount are allowed. The options are listed in the `nfs(5)` man page. Multiple options are separated with a comma.

**driverdisk** (optional)

Driver diskettes can be used during kickstart installations. You must copy the driver diskettes's contents to the root directory of a partition on the system's hard drive. Then you must use the `driverdisk` command to tell the installation program where to look for the driver disk.

```bash
driverdisk <partition> --source=<url> --biospart=<biospart> [--type=<fstype>]
```

Alternatively, a network location can be specified for the driver diskette:

```bash
driverdisk --source=ftp://path/to/dd.img
driverdisk --source=http://path/to/dd.img
driverdisk --source=nfs:host:/path/to/img
```

- `<partition>` — Partition containing the driver disk.
Kickstart Options

- `<url>` — URL for the driver disk. NFS locations can be given in the form `nfs:host:/path/to/img`.

- `<biospart>` — BIOS partition containing the driver disk (for example, 82p2).

- `--type=` — File system type (for example, vfat or ext2).

**firewall** (optional)

This option corresponds to the **Firewall Configuration** screen in the installation program:

```
firmware --enabled|--disabled [--trust=] <device> [--port=]
```

- `--enabled` or `--enable` — Reject incoming connections that are not in response to outbound requests, such as DNS replies or DHCP requests. If access to services running on this machine is needed, you can choose to allow specific services through the firewall.

- `--disabled` or `--disable` — Do not configure any iptables rules.

- `--trust=` — Listing a device here, such as eth0, allows all traffic coming from that device to go through the firewall. To list more than one device, use `--trust eth0 --trust eth1`. Do NOT use a comma-separated format such as `--trust eth0, eth1`.

- `<incoming>` — Replace with one or more of the following to allow the specified services through the firewall.
  - `--ssh`
  - `--telnet`
  - `--smtp`
  - `--http`
  - `--ftp`

- `--port=` — You can specify that ports be allowed through the firewall using the port:protocol format. For example, to allow IMAP access through your firewall, specify `imap:tcp`. Numeric ports can also be specified explicitly; for example, to allow UDP packets on port 1234 through, specify `1234:udp`. To specify multiple ports, separate them by commas.

**firstboot** (optional)

Determine whether the **Firstboot** starts the first time the system is booted. If enabled, the `firstboot` package must be installed. If not specified, this option is disabled by default.

- `--enable` or `--enabled` — The **Setup Agent** is started the first time the system boots.

- `--disable` or `--disabled` — The **Setup Agent** is not started the first time the system boots.

- `--reconfig` — Enable the **Setup Agent** to start at boot time in reconfiguration mode. This mode enables the language, mouse, keyboard, root password, security level, time zone, and networking configuration options in addition to the default ones.

**graphical** (optional)

Perform the kickstart installation in graphical mode. This is the default.
Chapter 14. Kickstart Installations

**halt (optional)**

Halt the system after the installation has successfully completed. This is similar to a manual installation, where anaconda displays a message and waits for the user to press a key before rebooting. During a kickstart installation, if no completion method is specified, this option is used as the default.

The **halt** option is roughly equivalent to the **shutdown -h** command.

For other completion methods, refer to the **poweroff**, **reboot**, and **shutdown** kickstart options.

**install (optional)**

Tells the system to install a fresh system rather than upgrade an existing system. This is the default mode. For installation, you must specify the type of installation from **cdrom**, **harddrive**, **nfs**, or **url** (for FTP or HTTP installations). The **install** command and the installation method command must be on separate lines.

- **cdrom** — Install from the first optical drive on the system.

- **harddrive** — Install from a Red Hat installation tree on a local drive, which must be either vfat or ext2.
  - **--biospart=**
    
    BIOS partition to install from (such as 82).
  - **--partition=**
    
    Partition to install from (such as sdb2).
  - **--dir=**
    
    Directory containing the **variant** directory of the installation tree.

  For example:

  ```
  harddrive --partition=hdb2 --dir=/tmp/install-tree
  ```

- **nfs** — Install from the NFS server specified.
  - **--server=**
    
    Server from which to install (hostname or IP).
  - **--dir=**
    
    Directory containing the **variant** directory of the installation tree.
  - **--opts=**
    
    Mount options to use for mounting the NFS export. (optional)

  For example:

  ```
  nfs --server=nfsserver.example.com --dir=/tmp/install-tree
  ```

- **url** — Install from an installation tree on a remote server via FTP or HTTP.
For example:

```
url --url http://<server>/<dir>
```

or:

```
url --url ftp://<username>:<password>@<server>/<dir>
```

**interactive** (optional)

Uses the information provided in the kickstart file during the installation, but allow for inspection and modification of the values given. You are presented with each screen of the installation program with the values from the kickstart file. Either accept the values by clicking Next or change the values and click Next to continue. Refer to the autostep command.

**iscsi** (optional)

```
iscsi --ipaddr= [options].
```

Specifies additional iSCSI storage to be attached during installation. If you use the *iscsi* parameter, you must also assign a name to the iSCSI node, using the *iscsiname* parameter. The *iscsiname* parameter must appear before the *iscsi* parameter in the kickstart file.

We recommend that wherever possible you configure iSCSI storage in the system BIOS or firmware (iBFT for Intel systems) rather than use the *iscsi* parameter. Anaconda automatically detects and uses disks configured in BIOS or firmware and no special configuration is necessary in the kickstart file.

If you must use the *iscsi* parameter, ensure that networking is activated at the beginning of the installation, and that the *iscsi* parameter appears in the kickstart file before you refer to iSCSI disks with parameters such as *clearpart* or *ignoredisk*.

- **--port=** (mandatory) — the port number (typically, **--port=3260**)
- **--user=** — the username required to authenticate with the target
- **--password=** — the password that corresponds with the username specified for the target
- **--reverse-user=** — the username required to authenticate with the initiator from a target that uses reverse CHAP authentication
- **--reverse-password=** — the password that corresponds with the username specified for the initiator

**iscsiname** (optional)

Assigns a name to an iSCSI node specified by the *iscsi* parameter. If you use the *iscsi* parameter in your kickstart file, this parameter is mandatory, and you must specify *iscsiname* in the kickstart file before you specify *iscsi*.

**key** (optional)

Specify an installation key, which is needed to aid in package selection and identify a Red Hat Enterprise Linux system for support purposes. This command is specific to Red Hat Enterprise Linux and is meaningless in Fedora.

- **--skip** — Skip entering a key. Usually if the key command is not given, anaconda will pause at this step to prompt for a key. This option allows automated installation to continue if you do not have a key or do not want to provide one.
keyboard (required)

Sets system keyboard type. Here is the list of available keyboards on i386 and Alpha machines:

be-latin1, bg, br-abnt2, cf, cz-lat2, cz-us-qwertz, de, de-latin1, de-latin1-nodeadkeys, dk, dk-latin1, dvorak, es, et, fi, fi-latin1, fr, fr-latin0, fr-latin1, fr-pc, fr_CH, fr_CH-latin1, gr, hu, hu101, is-latin1, it, it-ibm, it2, jp106, la-latin1, mk-utf, no, no-latin1, pl, pt-latin1, ro_win, ru, ru-cpi251, ru-ms, ru1, ru2, ru_win, se-latin1, sg, sg-latin1, sk-qwerty, slovene, speakup, speakup-lt, sv-latin1, sg, sg-latin1, sk-qwerty, slovene, trq, ua, uk, us, usacentos

The file /usr/lib/python2.2/site-packages/rhpl/keyboard_models.py also contains this list and is part of the rhpl package.

lang (required)

Sets the language to use during installation and the default language to use on the installed system. For example, to set the language to English, the kickstart file should contain the following line:

lang en_US

The file /usr/share/system-config-language/locale-list provides a list of the valid language codes in the first column of each line and is part of the system-config-language package.

Certain languages (mainly Chinese, Japanese, Korean, and Indic languages) are not supported during text mode installation. If one of these languages is specified using the lang command, installation will continue in English though the running system will have the specified language by default.

langsupport (deprecated)

The langsupport keyword is deprecated and its use will cause an error message to be printed to the screen and installation to halt. Instead of using the langsupport keyword, you should now list the package group names for all languages you want supported in the %packages section of your kickstart file. For instance, adding support for French means you should add the following to %packages:

@french-support

logvol (optional)

Create a logical volume for Logical Volume Management (LVM) with the syntax:

logvol <mntpoint> --vgname=<name> --size=<size> --name=<name> <options>

The options are as follows:

• --noformat — Use an existing logical volume and do not format it.
• --useexisting — Use an existing logical volume and reformat it.
• --fstype= — Sets the file system type for the logical volume. Valid values are xfs, ext2, ext3, ext4, swap, vfat, and hfs.
• **--fsoptions=** — Specifies a free form string of options to be used when mounting the filesystem. This string will be copied into the `/etc/fstab` file of the installed system and should be enclosed in quotes.

• **--bytes-per-inode=** — Specifies the size of inodes on the filesystem to be made on the logical volume. Not all filesystems support this option, so it is silently ignored for those cases.

• **--grow=** — Tells the logical volume to grow to fill available space (if any), or up to the maximum size setting.

• **--maxsize=** — The maximum size in megabytes when the logical volume is set to grow. Specify an integer value here, and do not append the number with MB.

• **--recommended=** — Determine the size of the logical volume automatically.

• **--percent=** — Specify the size of the logical volume as a percentage of available space in the volume group.

• **--encrypted** — Specifies that this logical volume should be encrypted.

• **--passphrase=** — Specifies the passphrase to use when encrypting this logical volume. Without the above **--encrypted** option, this option does nothing. If no passphrase is specified, the default system-wide one is used, or the installer will stop and prompt if there is no default.

• **--escrowcert=URL_of_X.509_certificate** — Store data encryption keys of all encrypted volumes as files in `/ (root)`, encrypted using the X.509 certificate from the URL specified with `URL_of_X.509_certificate`. The keys are stored as a separate file for each encrypted volume. This option is only meaningful if **--encrypted** is specified.

• **--backuppassphrase=** — Add a randomly-generated passphrase to each encrypted volume. Store these passphrases in separate files in `/ (root)`, encrypted using the X.509 certificate specified with **--escrowcert**. This option is only meaningful if **--escrowcert** is specified.

Create the partition first, create the logical volume group, and then create the logical volume. For example:

```bash
part pv.01 --size 3000
volgroup myvg pv.01
logvol / --vgname=myvg --size=2000 --name=rootvol
```

**logging** *(optional)*

This command controls the error logging of anaconda during installation. It has no effect on the installed system.

• **--host=** — Send logging information to the given remote host, which must be running a syslogd process configured to accept remote logging.

• **--port=** — If the remote syslogd process uses a port other than the default, it may be specified with this option.

• **--level=** — One of debug, info, warning, error, or critical.

Specify the minimum level of messages that appear on tty3. All messages will still be sent to the log file regardless of this level, however.
Chapter 14. Kickstart Installations

mediacheck (optional)

If given, this will force anaconda to run mediacheck on the installation media. This command requires that installs be attended, so it is disabled by default.

monitor (optional)

If the monitor command is not given, anaconda will use X to automatically detect your monitor settings. Please try this before manually configuring your monitor.

- **--hsync=** — Specifies the horizontal sync frequency of the monitor.
- **--monitor=** — Use specified monitor; monitor name should be from the list of monitors in /usr/share/hwdata/MonitorsDB from the hwdata package. The list of monitors can also be found on the X Configuration screen of the Kickstart Configurator. This is ignored if --hsync or --vsync is provided. If no monitor information is provided, the installation program tries to probe for it automatically.
- **--noprobe=** — Do not try to probe the monitor.
- **--vsync=** — Specifies the vertical sync frequency of the monitor.

deprecated)

The mouse keyword is deprecated.

network (optional)

Configures network information for the system. If the kickstart installation does not require networking (in other words, it is not installed over NFS, HTTP, or FTP), networking is not configured for the system. If the installation does require networking and network information is not provided in the kickstart file, the installation program assumes that the installation should be done over eth0 via a dynamic IP address (BOOTP/DHCP), and configures the final, installed system to determine its IP address dynamically. The network option configures networking information for kickstart installations via a network as well as for the installed system.

- **--bootproto=** — One of dhcp, bootp, or static.

  It defaults to dhcp. bootp and dhcp are treated the same.

  The DHCP method uses a DHCP server system to obtain its networking configuration. As you might guess, the BOOTP method is similar, requiring a BOOTP server to supply the networking configuration. To direct a system to use DHCP:

  ```
  network --bootproto=dhcp
  ```

  To direct a machine to use BOOTP to obtain its networking configuration, use the following line in the kickstart file:

  ```
  network --bootproto=bootp
  ```

  The static method requires that you enter all the required networking information in the kickstart file. As the name implies, this information is static and is used during and after the installation. The line for static networking is more complex, as you must include all network configuration information on one line. You must specify the IP address, netmask, gateway, and nameserver.
Note that although the presentation of this example on this page has broken the line, in a real kickstart file, you must include all this information on a single line with no break.

```
network --bootproto=static --ip=10.0.2.15 --netmask=255.255.255.0
--gateway=10.0.2.254 --nameserver=10.0.2.1
```

If you use the static method, be aware of the following two restrictions:

- All static networking configuration information must be specified on one line; you cannot wrap lines using a backslash, for example.

- You can also configure multiple nameservers here. To do so, specify them as a comma-delimited list in the command line.

Note that although the presentation of this example on this page has broken the line, in a real kickstart file, you must include all this information on a single line with no break.

```
network --bootproto=static --ip=10.0.2.15 --netmask=255.255.255.0
--gateway=10.0.2.254 --nameserver 192.168.2.1,192.168.3.1
```

- `--device=` — Used to select a specific Ethernet device for installation. Note that using `--device=` is not effective unless the kickstart file is a local file (such as `ks=hd`), since the installation program configures the network to find the kickstart file. For example:

```
network --bootproto= dhcp --device=eth0
```

- `--ip=` — IP address for the machine to be installed.
- `--gateway=` — Default gateway as an IP address.
- `--nameserver=` — Primary nameserver, as an IP address.
- `--nodns` — Do not configure any DNS server.
- `--netmask=` — Netmask for the installed system.
- `--hostname=` — Hostname for the installed system.
- `--ethtool=` — Specifies additional low-level settings for the network device which will be passed to the ethtool program.
- `--essid=` — The network ID for wireless networks.
- `--wepkey=` — The encryption key for wireless networks.
- `--onboot=` — Whether or not to enable the device at boot time.
- `--dhcpclass=` — The DHCP class.
- `--mtu=` — The MTU of the device.
- `--noipv4` — Disable IPv4 on this device.
- `--noipv6` — Disable IPv6 on this device.
Chapter 14. Kickstart Installations

**multipath** (optional)

```
multipath --name= --device= --rule=
```

**part** or **partition** (required for installs, ignored for upgrades)

Creates a partition on the system.

If more than one Fedora installation exists on the system on different partitions, the installation program prompts the user and asks which installation to upgrade.

**Warning**

All partitions created are formatted as part of the installation process unless **--noformat** and **--onpart** are used.

**Important**

If you select text mode for a kickstart installation, make sure that you specify choices for the partitioning, bootloader, and package selection options. These steps are automated in text mode, and **anaconda** cannot prompt you for missing information. If you do not provide choices for these options, **anaconda** will stop the installation process.

For a detailed example of **part** in action, refer to Section 14.4.1, "Advanced Partitioning Example".

- `<mntpoint>` — The `<mntpoint>` is where the partition is mounted and must be of one of the following forms:
  - `/<path>`
    
    For example, `/`, `/usr`, `/home`
  - `swap`
    
    The partition is used as swap space.

    To determine the size of the swap partition automatically, use the **--recommended** option:

    ```
    swap --recommended
    ```

    The recommended maximum swap size for machines with less than 2GB of RAM is twice the amount of RAM. For machines with 2GB or more, this recommendation changes to 2GB plus the amount of RAM.

- `raid.<id>`

  The partition is used for software RAID (refer to **raid**).

- `pv.<id>`

  The partition is used for LVM (refer to **logvol**).
• **--size** = — The minimum partition size in megabytes. Specify an integer value here such as 500. Do not append the number with MB.

• **--grow** — Tells the partition to grow to fill available space (if any), or up to the maximum size setting.

**Note**

If you use **--grow** without setting **--maxsize** on a swap partition, Anaconda will limit the maximum size of the swap partition. For systems that have less than 2GB of physical memory, the imposed limit is twice the amount of physical memory. For systems with more than 2GB, the imposed limit is the size of physical memory plus 2GB.

• **--maxsize** = — The maximum partition size in megabytes when the partition is set to grow. Specify an integer value here, and do not append the number with MB.

• **--noformat** — Tells the installation program not to format the partition, for use with the **--onpart** command.

• **--onpart** = or **--usepart** = — Put the partition on the already existing device. For example:

```bash
partition /home --onpart=hda1
```

puts /home on /dev/hda1, which must already exist.

• **--ondisk** = or **--ondrive** = — Forces the partition to be created on a particular disk. For example, **--ondisk=sdb** puts the partition on the second SCSI disk on the system.

• **--asprimary** — Forces automatic allocation of the partition as a primary partition, or the partitioning fails.

• **--type** = (replaced by **fstype**) — This option is no longer available. Use **fstype**.

• **--fstype** = — Sets the file system type for the partition. Valid values are **xfs**, **ext2**, **ext3**, **ext4**, **swap**, **vfat**, and **hfs**.

• **--bytes-per-inode** = — Specifies the size of inodes on the filesystem to be made on the partition. Not all filesystems support this option, so it is silently ignored for those cases.

• **--recommended** — Determine the size of the partition automatically.

• **--onbiosdisk** — Forces the partition to be created on a particular disk as discovered by the BIOS.

• **--fsoptions** — Specifies a free form string of options to be used when mounting the filesystem. This string will be copied into the /etc/fstab file of the installed system and should be enclosed in quotes.

• **--encrypted** — Specifies that this partition should be encrypted.

• **--passphrase** = — Specifies the passphrase to use when encrypting this partition. Without the above **--encrypted** option, this option does nothing. If no passphrase is specified, the default system-wide one is used, or the installer will stop and prompt if there is no default.
Chapter 14. Kickstart Installations

- **--escrowcert=URL_of_X.509_certificate** — Store data encryption keys of all encrypted partitions as files in / (root), encrypted using the X.509 certificate from the URL specified with `URL_of_X.509_certificate`. The keys are stored as a separate file for each encrypted partition. This option is only meaningful if **--encrypted** is specified.

- **--backuppassphrase=** — Add a randomly-generated passphrase to each encrypted partition. Store these passphrases in separate files in / (root), encrypted using the X.509 certificate specified with **--escrowcert**. This option is only meaningful if **--escrowcert** is specified.

**Note**

If partitioning fails for any reason, diagnostic messages appear on virtual console 3.

**poweroff** (optional)

Shut down and power off the system after the installation has successfully completed. Normally during a manual installation, anaconda displays a message and waits for the user to press a key before rebooting. During a kickstart installation, if no completion method is specified, the **halt** option is used as default.

The **poweroff** option is roughly equivalent to the **shutdown -p** command.

**Note**

The **poweroff** option is highly dependent on the system hardware in use. Specifically, certain hardware components such as the BIOS, APM (advanced power management), and ACPI (advanced configuration and power interface) must be able to interact with the system kernel. Contact your manufacturer for more information on your system's APM/ACPI abilities.

For other completion methods, refer to the **halt**, **reboot**, and **shutdown** kickstart options.

**raid** (optional)

Assembles a software RAID device. This command is of the form:

```
raid <mntpoint> --level=<level> --device=<mddevice> <partitions*>  
```

- **<mntpoint>** — Location where the RAID file system is mounted. If it is /, the RAID level must be 1 unless a boot partition (/boot) is present. If a boot partition is present, the /boot partition must be level 1 and the root (/) partition can be any of the available types. The `<partitions*>` (which denotes that multiple partitions can be listed) lists the RAID identifiers to add to the RAID array.

- **--level=** — RAID level to use (0, 1, or 5).

- **--device=** — Name of the RAID device to use (such as md0 or md1). RAID devices range from md0 to md15, and each may only be used once.

- **--bytes-per-inode=** — Specifies the size of inodes on the filesystem to be made on the RAID device. Not all filesystems support this option, so it is silently ignored for those cases.
Kickstart Options

- **--spares=** — Specifies the number of spare drives allocated for the RAID array. Spare drives are used to rebuild the array in case of drive failure.

- **--fstype=** — Sets the file system type for the RAID array. Valid values are xfs, ext2, ext3, ext4, swap, vfat, and hfs.

- **--fsoptions=** — Specifies a free form string of options to be used when mounting the filesystem. This string will be copied into the /etc/fstab file of the installed system and should be enclosed in quotes.

- **--noformat** — Use an existing RAID device and do not format the RAID array.

- **--useexisting** — Use an existing RAID device and reformat it.

- **--encrypted** — Specifies that this RAID device should be encrypted.

- **--passphrase=** — Specifies the passphrase to use when encrypting this RAID device. Without the above **--encrypted** option, this option does nothing. If no passphrase is specified, the default system-wide one is used, or the installer will stop and prompt if there is no default.

- **--escrowcert=** — Store the data encryption key for this device in a file in / (root), encrypted using the X.509 certificate from the URL specified with **URL_of_X.509_certificate**. This option is only meaningful if **--encrypted** is specified.

- **--backuppassphrase=** — Add a randomly-generated passphrase to this device. Store the passphrase in a file in / (root), encrypted using the X.509 certificate specified with **--escrowcert**. This option is only meaningful if **--escrowcert** is specified.

The following example shows how to create a RAID level 1 partition for /, and a RAID level 5 for /usr, assuming there are three SCSI disks on the system. It also creates three swap partitions, one on each drive.

```bash
part raid.01 --size=60 --ondisk=sda
part raid.02 --size=60 --ondisk=sdb
part raid.03 --size=60 --ondisk=sdc

part swap --size=128 --ondisk=sda
part swap --size=128 --ondisk=sdb
part swap --size=128 --ondisk=sdc

part raid.11 --size=1 --grow --ondisk=sda
part raid.12 --size=1 --grow --ondisk=sdb
part raid.13 --size=1 --grow --ondisk=sdc

raid / --level=1 --device=md0 raid.01 raid.02 raid.03
raid /usr --level=5 --device=md1 raid.11 raid.12 raid.13
```

For a detailed example of **raid** in action, refer to Section 14.4.1, "Advanced Partitioning Example".

**reboot** (optional)
Reboot after the installation is successfully completed (no arguments). Normally, kickstart displays a message and waits for the user to press a key before rebooting.

The **reboot** option is roughly equivalent to the **shutdown -r** command.
Specify **reboot** to automate installation fully when installing in cmdline mode on System z.

For other completion methods, refer to the **halt**, **poweroff**, and **shutdown** kickstart options.

The **halt** option is the default completion method if no other methods are explicitly specified in the kickstart file.

**Note**

Use of the **reboot** option may result in an endless installation loop, depending on the installation media and method.

**repo** (optional)

Configures additional yum repositories that may be used as sources for package installation. Multiple repo lines may be specified.

```bash
repo --name=<repoid> [--baseurl=<url]| --mirrorlist=<url>]
```

- **--name** — The repo id. This option is required.
- **--baseurl** — The URL for the repository. The variables that may be used in yum repo config files are not supported here. You may use one of either this option or --mirrorlist, not both.
- **--mirrorlist** — The URL pointing at a list of mirrors for the repository. The variables that may be used in yum repo config files are not supported here. You may use one of either this option or --baseurl, not both.

**rootpw** (required)

Sets the system's root password to the **<password>** argument.

```bash
rootpw [--iscrypted] <password>
```

- **--iscrypted** — If this is present, the password argument is assumed to already be encrypted.

**selinux** (optional)

Sets the state of SELinux on the installed system. SELinux defaults to enforcing in anaconda.

```bash
selinux [--disabled|--enforcing|--permissive]
```

- **--enforcing** — Enables SELinux with the default targeted policy being enforced.

**Note**

If the **selinux** option is not present in the kickstart file, SELinux is enabled and set to **--enforcing** by default.

- **--permissive** — Outputs warnings based on the SELinux policy, but does not actually enforce the policy.
- **--disabled** — Disables SELinux completely on the system.
For more information regarding SELinux for Fedora, refer to the *Fedora Security Enhanced Linux User Guide*.

**services** (optional)

Modifies the default set of services that will run under the default runlevel. The services listed in the disabled list will be disabled before the services listed in the enabled list are enabled.

- **--disabled** — Disable the services given in the comma separated list.
- **--enabled** — Enable the services given in the comma separated list.

**Do not include spaces in the list of services**

If you include spaces in the comma-separated list, kickstart will enable or disable only the services up to the first space. For example:

```
services --disabled auditd, cups,smartd, nfslock
```

will disable only the *auditd* service. To disable all four services, this entry should include no spaces between services:

```
services --disabled auditd,cups,smartd,nfslock
```

**shutdown** (optional)

Shut down the system after the installation has successfully completed. During a kickstart installation, if no completion method is specified, the *halt* option is used as default.

The **shutdown** option is roughly equivalent to the *shutdown* command.

For other completion methods, refer to the *halt*, *poweroff*, and *reboot* kickstart options.

**skipx** (optional)

If present, X is not configured on the installed system.

**sshpw** (optional)

The installer can start *ssh* to provide interactivity and inspection. This command controls the accounts created in the installation environment that may be remotely logged into. Each instance of this command creates a user. These users will not be created on the final system — they only exist for use while the installer is running.

```
sshpw --username=<name> <password> [--iscrypted|--plaintext] [--lock]
```

- **--username** — Provides the name of the user. This option is required.
- **--iscrypted** — If this is present, the password argument is assumed to already be encrypted. **--plaintext** has the opposite effect — the password argument is assumed to not be encrypted.
- **--lock** — If this is present, the new user account is locked by default. That is, the user will not be able to login from the console.

**text** (optional)

Perform the kickstart installation in text mode. Kickstart installations are performed in graphical mode by default.
Important

If you select text mode for a kickstart installation, make sure that you specify choices for the partitioning, bootloader, and package selection options. These steps are automated in text mode, and `anaconda` cannot prompt you for missing information. If you do not provide choices for these options, `anaconda` will stop the installation process.

**timezone** (required)
Sets the system time zone to `<timezone>` which may be any of the time zones listed by `timeconfig`.

```
timezone [--utc] <timezone>
```

- `--utc` — If present, the system assumes the hardware clock is set to UTC (Greenwich Mean) time.

**upgrade** (optional)
Tells the system to upgrade an existing system rather than install a fresh system. You must specify one of `cdrom`, `harddrive`, `nfs`, or `url` (for FTP and HTTP) as the location of the installation tree. Refer to `install` for details.

**user** (optional)
Creates a new user on the system.

```
user --name=<username> [--groups=<list>] [--homedir=<homedir>] [--password=<password>]
[--iscrypted] [--shell=<shell>] [--uid=<uid>]
```

- `--name=` — Provides the name of the user. This option is required.

- `--groups=` — In addition to the default group, a comma separated list of group names the user should belong to. The groups must exist before the user account is created.

- `--homedir=` — The home directory for the user. If not provided, this defaults to `/home/<username>`.

- `--password=` — The new user's password. If not provided, the account will be locked by default.

- `--iscrypted=` — Is the password provided by `--password` already encrypted or not?

- `--shell=` — The user's login shell. If not provided, this defaults to the system default.

- `--uid=` — The user's UID. If not provided, this defaults to the next available non-system UID.

**vnc** (optional)
Allows the graphical installation to be viewed remotely via VNC. This method is usually preferred over text mode, as there are some size and language limitations in text installs. With no options, this command will start a VNC server on the machine with no password and will print out the command that needs to be run to connect a remote machine.

```
vnc [--host=<hostname>] [--port=<port>] [--password=<password>]
```
• **--host=** — Instead of starting a VNC server on the install machine, connect to the VNC viewer process listening on the given hostname.

• **--port=** — Provide a port that the remote VNC viewer process is listening on. If not provided, anaconda will use the VNC default.

• **--password=** — Set a password which must be provided to connect to the VNC session. This is optional, but recommended.

**volgroup** *(optional)*
Use to create a Logical Volume Management (LVM) group with the syntax:

```
volgroup <name> <partition> <options>
```

The options are as follows:

• **--noformat** — Use an existing volume group and do not format it.

• **--useexisting** — Use an existing volume group and reformat it.

• **--pesize=** — Set the size of the physical extents.

Create the partition first, create the logical volume group, and then create the logical volume. For example:

```
part pv.01 --size 3000
volgroup myvg pv.01
logvol / --vgname=myvg --size=2000 --name=rootvol
```

For a detailed example of **volgroup** in action, refer to *Section 14.4.1, “Advanced Partitioning Example”*.  

**xconfig** *(optional)*
Configures the X Window System. If this option is not given, the user must configure X manually during the installation, if X was installed; this option should not be used if X is not installed on the final system.

• **--driver** — Specify the X driver to use for the video hardware.

• **--videoram=** — Specifies the amount of video RAM the video card has.

• **--defaultdesktop=** — Specify either GNOME or KDE to set the default desktop (assumes that GNOME Desktop Environment and/or KDE Desktop Environment has been installed through **%packages**).

• **--startxonboot** — Use a graphical login on the installed system.

• **--depth=** — Specify the default color depth for the X Window System on the installed system. Valid values are 8, 16, 24, and 32. Be sure to specify a color depth that is compatible with the video card and monitor.

**zerombr** *(optional)*
If **zerombr** is specified any invalid partition tables found on disks are initialized. This destroys all of the contents of disks with invalid partition tables.

Specific to System z: If **zerombr** is specified, any DASD visible to the installer which is not already low-level formatted gets automatically low-level formatted with **dasdfmt**. The command
also prevents user choice during interactive installations. If `zerombr` is not specified and there is at least one unformatted DASD visible to the installer, a non-interactive kickstart installation will exit unsuccessfully. If `zerombr` is not specified and there is at least one unformatted DASD visible to the installer, an interactive installation exits if the user does not agree to format all visible and unformatted DASDs. To circumvent this, only activate those DASDs that you will use during installation. You can always add more DASDs after installation is complete.

Note that this command was previously specified as `zerombr yes`. This form is now deprecated; you should now simply specify `zerombr` in your kickstart file instead.

`zfcp` (optional)
Define a Fiber channel device (IBM System z).

```
zfcp [--devnum=<devnum>] [--wwpn=<wwpn>] [--fcplun=<fcplun>]
```

`%include` (optional)
Use the `%include /path/to/file` command to include the contents of another file in the kickstart file as though the contents were at the location of the `%include` command in the kickstart file.

### 14.4.1. Advanced Partitioning Example

The following is a single, integrated example showing the `clearpart`, `raid`, `part`, `volgroup`, and `logvol` kickstart options in action:

```bash
# Raid 1 IDE config
clearpart --drives=hda,hdc --initlabel
part raid.11 --size 1000 --asprimary --ondrive=hda
part raid.12 --size 1000 --asprimary --ondrive=hda
part raid.13 --size 2000 --asprimary --ondrive=hda
part raid.14 --size 8000 --ondrive=hda
part raid.15 --size 1 --grow --ondrive=hda
part raid.21 --size 1000 --asprimary --ondrive=hdc
part raid.22 --size 1000 --asprimary --ondrive=hdc
part raid.23 --size 2000 --asprimary --ondrive=hdc
part raid.24 --size 8000 --ondrive=hdc
part raid.25 --size 1 --grow --ondrive=hdc

# You can add --spares=x
raid / --fstype ext3 --device md0 --level=RAID1 raid.11 raid.21
raid /safe --fstype ext3 --device md1 --level=RAID1 raid.12 raid.22
raid swap --fstype swap --device md2 --level=RAID1 raid.13 raid.23
raid /usr --fstype ext3 --device md3 --level=RAID1 raid.14 raid.24
raid pv.01 --fstype ext3 --device md4 --level=RAID1 raid.15 raid.25

# LVM configuration so that we can resize /var and /usr/local later
volgroup sysvg pv.01
logvol /var --vgname=sysvg --size=8000 --name=var
logvol /var/freespace --vgname=sysvg --size=8000 --name=freespacetouse
logvol /usr/local --vgname=sysvg --size=1 --grow --name=usrlocal
```

This advanced example implements LVM over RAID, as well as the ability to resize various directories for future growth.
14.5. Package Selection

**Warning — @Everything is not supported**

You can use a kickstart file to install every available package by specifying @Everything or simply * in the %packages section. Red Hat does not support this type of installation.

Moreover, using a kickstart file in this way will introduce package and file conflicts onto the installed system. Packages known to cause such problems are assigned to the @Conflicts (variant) group, where variant is Server or Client. If you specify @Everything in a kickstart file, be sure to exclude @Conflicts (variant) or the installation will fail:

```
@Everything (Server)
-@Conflicts
```

Note that Red Hat does not support the use of @Everything in a kickstart file, even if you exclude @Conflicts (variant).

Use the %packages command to begin a kickstart file section that lists the packages you would like to install (this is for installations only, as package selection during upgrades is not supported).

Packages can be specified by group or by individual package name, including with globs using the asterisk. The installation program defines several groups that contain related packages. Refer to the variant/repopdata/comps-*.xml file on the Fedora DVD for a list of groups. Each group has an id, user visibility value, name, description, and package list. In the package list, the packages marked as mandatory are always installed if the group is selected, the packages marked default are selected by default if the group is selected, and the packages marked optional must be specifically selected even if the group is selected to be installed.

In most cases, it is only necessary to list the desired groups and not individual packages. Note that the Core and Base groups are always selected by default, so it is not necessary to specify them in the %packages section.

Here is an example %packages selection:

```
%packages
 @ X Window System
 @ GNOME Desktop Environment
 @ Graphical Internet
 @ Sound and Video
dhcp
```

As you can see, groups are specified, one to a line, starting with an @ symbol, a space, and then the full group name as given in the comps.xml file. Groups can also be specified using the id for the group, such as gnome-desktop. Specify individual packages with no additional characters (the dhcp line in the example above is an individual package).

You can also specify which packages not to install from the default package list:

```
-autofs
```

The following options are available for the %packages option:
--nobase
Do not install the @Base group. Use this option to perform a minimal installation, for example, for a single-purpose server or desktop appliance.

--resolvedeps
The --resolvedeps option has been deprecated. Dependencies are resolved automatically every time now.

--ignoredeps
The --ignoredeps option has been deprecated. Dependencies are resolved automatically every time now.

--ignoremissing
Ignore the missing packages and groups instead of halting the installation to ask if the installation should be aborted or continued. For example:

```
%packages --ignoremissing
```

### 14.6. Pre-installation Script

You can add commands to run on the system immediately after the `ks.cfg` has been parsed. This section must be at the end of the kickstart file (after the commands) and must start with the `%pre` command. You can access the network in the `%pre` section; however, name service has not been configured at this point, so only IP addresses work.

> **Note**
> Note that the pre-install script is not run in the change root environment.

---

```
#interpreter /usr/bin/python
```

Allows you to specify a different scripting language, such as Python. Replace `/usr/bin/python` with the scripting language of your choice.

### 14.6.1. Example

Here is an example `%pre` section:

```
%pre
#!/bin/sh
hds=""
mymedia=""
for file in /proc/ide/h* do
    mymedia=`cat $file/media`
    if [ $mymedia == "disk" ] ; then
        hds="$hds `basename $file`"
    fi
done
set $hds
numhd=`echo $#`
drive1=`echo $hds | cut -d' ' -f1`
drive2=`echo $hds | cut -d' ' -f2`
#Write out partition scheme based on whether there are 1 or 2 hard drives
if [ $numhd == "2" ] ; then
    #2 drives
    echo "#partitioning scheme generated in %pre for 2 drives" > /tmp/part-include
    echo "clearpart --all" >> /tmp/part-include
```
This script determines the number of hard drives in the system and writes a text file with a different partitioning scheme depending on whether it has one or two drives. Instead of having a set of partitioning commands in the kickstart file, include the line:

```
%include /tmp/part-include
```

The partitioning commands selected in the script are used.

---

### Note

The pre-installation script section of kickstart cannot manage multiple install trees or source media. This information must be included for each created ks.cfg file, as the pre-installation script occurs during the second stage of the installation process.

---

### 14.7. Post-installation Script

You have the option of adding commands to run on the system once the installation is complete. This section must be at the end of the kickstart file and must start with the `%post` command. This section is useful for functions such as installing additional software and configuring an additional nameserver.

---

### Note

If you configured the network with static IP information, including a nameserver, you can access the network and resolve IP addresses in the `%post` section. If you configured the network for DHCP, the `/etc/resolv.conf` file has not been completed when the installation executes the `%post` section. You can access the network, but you cannot resolve IP addresses. Thus, if you are using DHCP, you must specify IP addresses in the `%post` section.

---

### Note

The post-install script is run in a chroot environment; therefore, performing tasks such as copying scripts or RPMs from the installation media do not work.

---

`--nochroot`

Allows you to specify commands that you would like to run outside of the chroot environment.

The following example copies the file `/etc/resolv.conf` to the file system that was just installed.
Chapter 14. Kickstart Installations

```
%post --nochroot
cp /etc/resolv.conf /mnt/sysimage/etc/resolv.conf
```

**--interpreter /usr/bin/python**

Allows you to specify a different scripting language, such as Python. Replace `/usr/bin/python` with the scripting language of your choice.

**--log /path/to/logfile**

Logs the output of the post-install script. Note that the path of the log file must take into account whether or not you use the **--nochroot** option. For example, without **--nochroot**:

```
%post --log=/root/ks-post.log
```

with **--nochroot**:

```
%post --nochroot --log=/mnt/sysimage/root/ks-post.log
```

### 14.7.1. Examples

Register the system to a Red Hat Network Satellite and log the output:

```
%post --log=/root/ks-post.log
wget -O- http://proxy-or-sat.example.com/pub/bootstrap_script | /bin/bash
/usr/sbin/rhnreg_ks --activationkey=<activationkey>
```

Run a script named `runme` from an NFS share:

```
mkdir /mnt/temp
mount -o nolock 10.10.0.2:/usr/new-machines /mnt/temp
openvt -s -w -- /mnt/temp/runme
umount /mnt/temp
```

**Note**

NFS file locking is **not** supported while in kickstart mode, therefore **-o nolock** is required when mounting an NFS mount.

### 14.8. Making the Kickstart File Available

A kickstart file must be placed in one of the following locations:

- On a boot diskette
- On a boot CD-ROM
- On a network

Normally a kickstart file is copied to the boot diskette, or made available on the network. The network-based approach is most commonly used, as most kickstart installations tend to be performed on networked computers.

Let us take a more in-depth look at where the kickstart file may be placed.
14.8.1. Creating Kickstart Boot Media

Diskette-based booting is no longer supported in Fedora. Installations must use CD-ROM or flash memory products for booting. However, the kickstart file may still reside on a diskette's top-level directory, and must be named `ks.cfg`.

To perform a CD-ROM-based kickstart installation, the kickstart file must be named `ks.cfg` and must be located in the boot CD-ROM's top-level directory. Since a CD-ROM is read-only, the file must be added to the directory used to create the image that is written to the CD-ROM. Refer to Section 3.3, “Making Minimal Boot Media” for instructions on creating boot media; however, before making the `file.iso` image file, copy the `ks.cfg` kickstart file to the `isolinux/` directory.

To perform a pen-based flash memory kickstart installation, the kickstart file must be named `ks.cfg` and must be located in the flash memory's top-level directory. Create the boot image first, and then copy the `ks.cfg` file.

Refer to Section 3.3, “Making Minimal Boot Media” for instructions on creating live USB media using the `boot.iso` image file that you can download from the Software & Download Center of the Red Hat customer portal.

**Note**

Creation of USB flashdrives for booting is possible, but is heavily dependent on system hardware BIOS settings. Refer to your hardware manufacturer to see if your system supports booting to alternate devices.

14.8.2. Making the Kickstart File Available on the Network

Network installations using kickstart are quite common, because system administrators can easily automate the installation on many networked computers quickly and painlessly. In general, the approach most commonly used is for the administrator to have both a BOOTP/DHCP server and an NFS server on the local network. The BOOTP/DHCP server is used to give the client system its networking information, while the actual files used during the installation are served by the NFS server. Often, these two servers run on the same physical machine, but they are not required to.

To perform a network-based kickstart installation, you must have a BOOTP/DHCP server on your network, and it must include configuration information for the machine on which you are attempting to install Fedora. The BOOTP/DHCP server provides the client with its networking information as well as the location of the kickstart file.

If a kickstart file is specified by the BOOTP/DHCP server, the client system attempts an NFS mount of the file's path, and copies the specified file to the client, using it as the kickstart file. The exact settings required vary depending on the BOOTP/DHCP server you use.

Here is an example of a line from the `dhcpd.conf` file for the DHCP server:

```
filename "/usr/new-machine/kickstart/"; next-server blarg.redhat.com;
```

Note that you should replace the value after `filename` with the name of the kickstart file (or the directory in which the kickstart file resides) and the value after `next-server` with the NFS server name.

If the file name returned by the BOOTP/DHCP server ends with a slash ("/"), then it is interpreted as a path only. In this case, the client system mounts that path using NFS, and searches for a particular file. The file name the client searches for is:
Chapter 14. Kickstart Installations

<ip-addr>-kickstart

The <ip-addr> section of the file name should be replaced with the client's IP address in dotted decimal notation. For example, the file name for a computer with an IP address of 10.10.0.1 would be 10.10.0.1-kickstart.

Note that if you do not specify a server name, then the client system attempts to use the server that answered the BOOTP/DHCP request as its NFS server. If you do not specify a path or file name, the client system tries to mount /kickstart from the BOOTP/DHCP server and tries to find the kickstart file using the same <ip-addr>-kickstart file name as described above.

14.9. Making the Installation Tree Available

The kickstart installation must access an installation tree. An installation tree is a copy of the binary Fedora DVD with the same directory structure.

If you are performing a DVD-based installation, insert the Fedora installation DVD into the computer before starting the kickstart installation.

If you are performing a hard drive installation, make sure the ISO images of the binary Fedora DVD are on a hard drive in the computer.

If you are performing a network-based (NFS, FTP, or HTTP) installation, you must make the installation tree or ISO image available over the network. Refer to Section 5.1, “Preparing for a Network Installation” for details.

14.10. Starting a Kickstart Installation

Important — Kickstart installations and Firstboot

Firstboot does not run after a system is installed from a Kickstart file unless a desktop and the X Window System were included in the installation and graphical login was enabled. Either specify a user with the user option in the Kickstart file before installing additional systems from it (refer to Section 14.4, “Kickstart Options” for details) or log into the installed system with a virtual console as root and add users with the adduser command.

To begin a kickstart installation, you must boot the system from boot media you have made or the Fedora DVD, and enter a special boot command at the boot prompt. The installation program looks for a kickstart file if the ks command line argument is passed to the kernel.

DVD and local storage

The linux ks= command also works if the ks.cfg file is located on a vfat or ext2 file system on local storage and you boot from the Fedora DVD.

With Driver Disk

If you need to use a driver disk with kickstart, specify the dd option as well. For example, to boot off a boot diskette and use a driver disk, enter the following command at the boot: prompt:

```
linux ks=hd:partition:/path/ks.cfg dd
```
Starting a Kickstart Installation

Boot CD-ROM
If the kickstart file is on a boot CD-ROM as described in Section 14.8.1, “Creating Kickstart Boot Media”, insert the CD-ROM into the system, boot the system, and enter the following command at the boot: prompt (where ks.cfg is the name of the kickstart file):

```
linux ks=cdrom:/ks.cfg
```

Other options to start a kickstart installation are as follows:

**askmethod**
Do not automatically use the DVD as the install source if we detect a Fedora DVD in your DVD drive.

**autostep**
Make kickstart non-interactive.

**debug**
Start up pdb immediately.

**dd**
Use a driver disk.

**dhcpclass=<class>**
Sends a custom DHCP vendor class identifier. ISC's dhcpcd can inspect this value using "option vendor-class-identifier".

**dns=<dns>**
Comma separated list of nameservers to use for a network installation.

**driverdisk**
Same as 'dd'.

**expert**
Turns on special features:
- allows partitioning of removable media
- prompts for a driver disk

**gateway=<gw>**
Gateway to use for a network installation.

**graphical**
Force graphical install. Required to have ftp/http use GUI.

**isa**
Prompt user for ISA devices configuration.

**ip=<ip>**
IP to use for a network installation, use 'dhcp' for DHCP.

**keymap=<keymap>**
Keyboard layout to use. Valid values are those which can be used for the 'keyboard' kickstart command.
Chapter 14. Kickstart Installations

ks=nfs:<server>:/<path>
The installation program looks for the kickstart file on the NFS server <server>, as file <path>. The installation program uses DHCP to configure the Ethernet card. For example, if your NFS server is server.example.com and the kickstart file is in the NFS share /mydir/ks.cfg, the correct boot command would be ks=nfs:server.example.com:/mydir/ks.cfg.

ks=http://<server>:/<path>
The installation program looks for the kickstart file on the HTTP server <server>, as file <path>. The installation program uses DHCP to configure the Ethernet card. For example, if your HTTP server is server.example.com and the kickstart file is in the HTTP directory /mydir/ks.cfg, the correct boot command would be ks=http://server.example.com/mydir/ks.cfg.

ks=hd:<device>:/<file>
The installation program mounts the file system on <device> (which must be vfat or ext2), and looks for the kickstart configuration file as <file> in that file system (for example, ks=hd:sda3:/mydir/ks.cfg).

ks.bd:<biosdev>:/<path>
The installation program mounts the file system on the specified partition on the specified BIOS device <biosdev>, and looks for the kickstart configuration file specified in <path> (for example, ks=bd:80p3:/mydir/ks.cfg). Note this does not work for BIOS RAID sets.

ks=file:/<file>
The installation program tries to read the file <file> from the file system; no mounts are done. This is normally used if the kickstart file is already on the initrd image.

ks=cdrom:/<path>
The installation program looks for the kickstart file on CD-ROM, as file <path>.

ks
If ks is used alone, the installation program configures the Ethernet card to use DHCP. The kickstart file is read from the “bootServer” from the DHCP response as if it is an NFS server sharing the kickstart file. By default, the bootServer is the same as the DHCP server. The name of the kickstart file is one of the following:

• If DHCP is specified and the boot file begins with a /, the boot file provided by DHCP is looked for on the NFS server.

• If DHCP is specified and the boot file begins with something other than a /, the boot file provided by DHCP is looked for in the /kickstart directory on the NFS server.

• If DHCP did not specify a boot file, then the installation program tries to read the file /kickstart/1.2.3.4-kickstart, where 1.2.3.4 is the numeric IP address of the machine being installed.

ksdevice=<device>
The installation program uses this network device to connect to the network. For example, consider a system connected to an NFS server through the eth1 device. To perform a kickstart installation on this system using a kickstart file from the NFS server, you would use the command ks=nfs::<server>:/<path> ksdevice=eth1 at the boot: prompt.

kssendmac
Adds HTTP headers to ks=http:// request that can be helpful for provisioning systems. Includes MAC address of all nics in CGI environment variables of the form: "X-RHN-Provisioning-MAC-0: eth0 01:23:45:67:89:ab".
Starting a Kickstart Installation

**lang=<lang>**
Language to use for the installation. This should be a language which is valid to be used with the ‘lang’ kickstart command.

**loglevel=<level>**
Set the minimum level required for messages to be logged. Values for <level> are debug, info, warning, error, and critical. The default value is info.

**mediacheck**
Activates loader code to give user option of testing integrity of install source (if an ISO-based method).

**netmask=<nm>**
Netmask to use for a network installation.

**nofallback**
If GUI fails exit.

**nofb**
Do not load the VGA16 framebuffer required for doing text-mode installation in some languages.

**nofirewire**
Do not load support for firewire devices.

**noipv6**
Disable IPv6 networking during installation.

**nomount**
Don’t automatically mount any installed Linux partitions in rescue mode.

**nonet**
Do not auto-probe network devices.

**noparport**
Do not attempt to load support for parallel ports.

**nopass**
Don’t pass keyboard/mouse info to stage 2 installer, good for testing keyboard and mouse config screens in stage2 installer during network installs.

**nopcmcia**
Ignore PCMCIA controller in system.

**noprobe**
Do not attempt to detect hw, prompts user instead.

**noshell**
Do not put a shell on tty2 during install.

---

*This option is not available during PXE installations*

During installations from a PXE server, IPv6 networking might become active before anaconda processes the Kickstart file. If so, this option will have no effect during installation.
Chapter 14. Kickstart Installations

nostorage
Do not auto-probe storage devices (SCSI, IDE, RAID).

nousb
Do not load USB support (helps if install hangs early sometimes).

nousbstorage
Do not load usbstorage module in loader. May help with device ordering on SCSI systems.

repo=cdrom
Do a DVD based installation.

repo=ftp://<path>
Use <path> for an FTP installation.

repo=hd:<dev>:<path>
Use <path> on <dev> for a hard drive installation.

repo=http://<path>
Use <path> for an HTTP installation.

repo=nfs:<path>
Use <path> for an NFS installation.

rescue
Run rescue environment.

resolution=<mode>
Run installer in mode specified, '1024x768' for example.

serial
Turns on serial console support.

skipddc
Skips DDC probe of monitor, may help if it's hanging system.

syslog=<host>[:<port>]
Once installation is up and running, send log messages to the syslog process on <host>, and optionally, on port <port>. Requires the remote syslog process to accept connections (the -r option).

text
Force text mode install.

Important

If you select text mode for a kickstart installation, make sure that you specify choices for the partitioning, bootloader, and package selection options. These steps are automated in text mode, and anaconda cannot prompt you for missing information. If you do not provide choices for these options, anaconda will stop the installation process.

updates
Prompt for storage device containing updates (bug fixes).
Starting a Kickstart Installation

(updates=ftp://<path>)
  Image containing updates over FTP.

(updates=http://<path>)
  Image containing updates over HTTP.

(upgradeany)
  Don't require an /etc/redhat-release that matches the expected syntax to upgrade.

(vnc)
  Enable vnc-based installation. You will need to connect to the machine using a vnc client application.

(vncconnect=<host>[:<port>])
  Once installation is up and running, connect to the vnc client named <host>, and optionally use port <port>.

  Requires 'vnc' option to be specified as well.

(vncpassword=<password>)
  Enable a password for the vnc connection. This will prevent someone from inadvertently connecting to the vnc-based installation.

  Requires 'vnc' option to be specified as well.
Chapter 15.

Kickstart Configurator

Kickstart Configurator allows you to create or modify a kickstart file using a graphical user interface, so that you do not have to remember the correct syntax of the file.

To use Kickstart Configurator, you must be running the X Window System and Kickstart Configurator must be installed on your system. To start Kickstart Configurator, select Applications (the main menu on the panel) => System Tools => Kickstart, or type the command /usr/sbin/system-config-kickstart. If Kickstart Configurator does not appear on the menu or you cannot start it from the command line, run su - yum install system-config-kickstart to make sure that the package is installed, or search for the package in your graphical package manager.

As you are creating a kickstart file, you can select File => Preview at any time to review your current selections.

To start with an existing kickstart file, select File => Open and select the existing file.

15.1. Basic Configuration

![Figure 15.1. Basic Configuration](image)

Choose the language to use during the installation and as the default language to be used after installation from the Default Language menu.

Select the system keyboard type from the Keyboard menu.

From the Time Zone menu, choose the time zone to use for the system. To configure the system to use UTC, select Use UTC clock.

Enter the desired root password for the system in the Root Password text entry box. Type the same password in the Confirm Password text box. The second field is to make sure you do not mistype the password and then realize you do not know what it is after you have completed the installation.
To save the password as an encrypted password in the file, select **Encrypt root password**. If the encryption option is selected, when the file is saved, the plain text password that you typed is encrypted and written to the kickstart file. Do not type an already encrypted password and select to encrypt it. Because a kickstart file is a plain text file that can be easily read, it is recommended that an encrypted password be used.

Choosing **Target Architecture** specifies which specific hardware architecture distribution is used during installation.

Choosing **Target Architecture** specifies which specific hardware architecture distribution is used during installation.

Choosing **Reboot system after installation** reboots your system automatically after the installation is finished.

Kickstart installations are performed in graphical mode by default. To override this default and use text mode instead, select the **Perform installation in text mode** option.

You can perform a kickstart installation in interactive mode. This means that the installation program uses all the options pre-configured in the kickstart file, but it allows you to preview the options in each screen before continuing to the next screen. To continue to the next screen, click the **Next** button after you have approved the settings or change them before continuing the installation. To select this type of installation, select the **Perform installation in interactive mode** option.

### 15.2. Installation Method

![Figure 15.2. Installation Method](image)

The **Installation Method** screen allows you to choose whether to perform a new installation or an upgrade. If you choose upgrade, the **Partition Information** and **Package Selection** options are disabled. They are not supported for kickstart upgrades.

Choose the type of kickstart installation or upgrade from the following options:
• **DVD** — Choose this option to install or upgrade from the Fedora DVD.

• **NFS** — Choose this option to install or upgrade from an NFS shared directory. In the text field for the the NFS server, enter a fully-qualified domain name or IP address. For the NFS directory, enter the name of the NFS directory that contains the `variant` directory of the installation tree. For example, if the NFS server contains the directory `/mirrors/redhat/i386/Server/`, enter `/mirrors/redhat/i386/` for the NFS directory.

• **FTP** — Choose this option to install or upgrade from an FTP server. In the FTP server text field, enter a fully-qualified domain name or IP address. For the FTP directory, enter the name of the FTP directory that contains the `variant` directory. For example, if the FTP server contains the directory `/mirrors/redhat/i386/Server/`, enter `/mirrors/redhat/i386/Server/` for the FTP directory. If the FTP server requires a username and password, specify them as well.

• **HTTP** — Choose this option to install or upgrade from an HTTP server. In the text field for the HTTP server, enter the fully-qualified domain name or IP address. For the HTTP directory, enter the name of the HTTP directory that contains the `variant` directory. For example, if the HTTP server contains the directory `/mirrors/redhat/i386/Server/`, enter `/mirrors/redhat/i386/Server/` for the HTTP directory.

• **Hard Drive** — Choose this option to install or upgrade from a hard drive. Hard drive installations require the use of ISO images. Be sure to verify that the ISO images are intact before you start the installation. To verify them, use an `md5sum` program as well as the `linux mediacheck boot` option as discussed in Section 10.6.2, “Verifying boot media”. Enter the hard drive partition that contains the ISO images (for example, `/dev/hda1`) in the Hard Drive Partition text box. Enter the directory that contains the ISO images in the Hard Drive Directory text box.

### 15.3. Boot Loader Options

<table>
<thead>
<tr>
<th>Basic Configuration</th>
<th>Boot Loader Options</th>

</tr>
<tr>
<td>Partition Information</td>
<td>Install new boot loader</td>
</tr>
<tr>
<td>Network Configuration</td>
<td>Do not install a boot loader</td>
</tr>
<tr>
<td>Authentication</td>
<td>Upgrade existing boot loader</td>
</tr>
<tr>
<td>Firewall Configuration</td>
<td><strong>GRUB Options:</strong></td>
</tr>
<tr>
<td>Display Configuration</td>
<td>☐ Use GRUB password</td>
</tr>
<tr>
<td>Package Selection</td>
<td>☐ Encrypt GRUB password</td>
</tr>
<tr>
<td>Pre-Installation Script</td>
<td>Install boot loader on Master Boot Record (MBR)</td>
</tr>
<tr>
<td>Post-Installation Script</td>
<td>Install boot loader on first sector of the boot partition</td>
</tr>
<tr>
<td>Kernel parameters:</td>
<td>☐ Install boot loader on first sector of the boot partition</td>
</tr>
</tbody>
</table>

![Figure 15.3. Boot Loader Options](image)

Please note that this screen will be disabled if you have specified a target architecture other than x86 / x86_64.
Chapter 15. Kickstart Configurator

GRUB is the default boot loader for Fedora on x86 / x86_64 architectures. If you do not want to install a boot loader, select **Do not install a boot loader**. If you choose not to install a boot loader, make sure you create a boot diskette or have another way to boot your system, such as a third-party boot loader.

You must choose where to install the boot loader (the Master Boot Record or the first sector of the `/boot` partition). Install the boot loader on the MBR if you plan to use it as your boot loader.

To pass any special parameters to the kernel to be used when the system boots, enter them in the **Kernel parameters** text field. For example, if you have an IDE CD-ROM Writer, you can tell the kernel to use the SCSI emulation driver that must be loaded before using `cdrecord` by configuring `hdd=ide-scsi` as a kernel parameter (where `hdd` is the CD-ROM device).

You can password protect the GRUB boot loader by configuring a GRUB password. Select **Use GRUB password**, and enter a password in the **Password** field. Type the same password in the **Confirm Password** text field. To save the password as an encrypted password in the file, select **Encrypt GRUB password**. If the encryption option is selected, when the file is saved, the plain text password that you typed is encrypted and written to the kickstart file. If the password you typed was already encrypted, unselect the encryption option.

If **Upgrade an existing installation** is selected on the **Installation Method** page, select **Upgrade existing boot loader** to upgrade the existing boot loader configuration, while preserving the old entries.

### 15.4. Partition Information

Select whether or not to clear the Master Boot Record (MBR). Choose to remove all existing partitions, remove all existing Linux partitions, or preserve existing partitions.

To initialize the disk label to the default for the architecture of the system (for example, `msdos` for x86), select **Initialize the disk label** if you are installing on a brand new hard drive.
Although anaconda and kickstart support Logical Volume Management (LVM), at present there is no mechanism for configuring this using the Kickstart Configurator.

15.4.1. Creating Partitions

To create a partition, click the Add button. The Partition Options window shown in Figure 15.5, “Creating Partitions” appears. Choose the mount point, file system type, and partition size for the new partition. Optionally, you can also choose from the following:

- In the Additional Size Options section, choose to make the partition a fixed size, up to a chosen size, or fill the remaining space on the hard drive. If you selected swap as the file system type, you can select to have the installation program create the swap partition with the recommended size instead of specifying a size.

- Force the partition to be created as a primary partition.

- Create the partition on a specific hard drive. For example, to make the partition on the first IDE hard disk (/dev/hda), specify hda as the drive. Do not include /dev in the drive name.

- Use an existing partition. For example, to make the partition on the first partition on the first IDE hard disk (/dev/hda1), specify hda1 as the partition. Do not include /dev in the partition name.

- Format the partition as the chosen file system type.
To edit an existing partition, select the partition from the list and click the **Edit** button. The same **Partition Options** window appears as when you chose to add a partition as shown in *Figure 15.5, “Creating Partitions”*, except it reflects the values for the selected partition. Modify the partition options and click **OK**.

To delete an existing partition, select the partition from the list and click the **Delete** button.

### 15.4.1.1. Creating Software RAID Partitions

To create a software RAID partition, use the following steps:

1. Click the **RAID** button.

2. Select **Create a software RAID partition**.

3. Configure the partitions as previously described, except select **Software RAID** as the file system type. Also, you must specify a hard drive on which to make the partition or specify an existing partition to use.
Figure 15.6. Creating a Software RAID Partition

Repeat these steps to create as many partitions as needed for your RAID setup. All of your partitions do not have to be RAID partitions.

After creating all the partitions needed to form a RAID device, follow these steps:

1. Click the RAID button.
2. Select Create a RAID device.
3. Select a mount point, file system type, RAID device name, RAID level, RAID members, number of spares for the software RAID device, and whether to format the RAID device.
4. Click **OK** to add the device to the list.
15.5. Network Configuration

If the system to be installed via kickstart does not have an Ethernet card, do not configure one on the Network Configuration page.

Networking is only required if you choose a networking-based installation method (NFS, FTP, or HTTP). Networking can always be configured after installation with the Network Administration Tool (system-config-network). Refer to the Fedora Deployment Guide for details.

For each Ethernet card on the system, click Add Network Device and select the network device and network type for the device. Select eth0 to configure the first Ethernet card, eth1 for the second Ethernet card, and so on.
15.6. Authentication

In the **Authentication** section, select whether to use shadow passwords and MD5 encryption for user passwords. These options are highly recommended and chosen by default.

The **Authentication Configuration** options allow you to configure the following methods of authentication:

- NIS
- LDAP
- Kerberos 5
- Hesiod
- SMB
- Name Switch Cache

These methods are not enabled by default. To enable one or more of these methods, click the appropriate tab, click the checkbox next to **Enable**, and enter the appropriate information for the authentication method. Refer to the Fedora Deployment Guide for more information about the options.

15.7. Firewall Configuration

The **Firewall Configuration** window is similar to the screen in the installation program and the **Security Level Configuration Tool**.
If **Disable firewall** is selected, the system allows complete access to any active services and ports. No connections to the system are refused or denied.

Selecting **Enable firewall** configures the system to reject incoming connections that are not in response to outbound requests, such as DNS replies or DHCP requests. If access to services running on this machine is required, you can choose to allow specific services through the firewall.

Only devices configured in the **Network Configuration** section are listed as available **Trusted devices**. Connections from any devices selected in the list are accepted by the system. For example, if **eth1** only receives connections from internal system, you might want to allow connections from it.

If a service is selected in the **Trusted services** list, connections for the service are accepted and processed by the system.

In the **Other ports** text field, list any additional ports that should be opened for remote access. Use the following format: `port:protocol`. For example, to allow IMAP access through the firewall, specify `imap:tcp`. Numeric ports can also be specified explicitly; to allow UDP packets on port 1234 through the firewall, enter `1234:udp`. To specify multiple ports, separate them with commas.

### 15.7.1. SELinux Configuration

Kickstart can set SELinux to **enforcing**, **permissive** or **disabled** mode. Finer grained configuration is not possible at this time.

### 15.8. Display Configuration

If you are installing the X Window System, you can configure it during the kickstart installation by checking the **Configure the X Window System** option on the **Display Configuration** window as shown in **Figure 15.11, “X Configuration”**. If this option is not chosen, the X configuration options are disabled and the **skipx** option is written to the kickstart file.
Chapter 15. Kickstart Configurator

Figure 15.11. X Configuration

Also select whether to start the **Setup Agent** the first time the system is rebooted. It is disabled by default, but the setting can be changed to enabled or enabled in reconfiguration mode. Reconfiguration mode enables the language, mouse, keyboard, root password, security level, time zone, and networking configuration options in addition to the default ones.

### 15.9. Package Selection

Figure 15.12. Package Selection

The **Package Selection** window allows you to choose which package groups to install.
Package resolution is carried out automatically.

Currently, Kickstart Configurator does not allow you to select individual packages. To install individual packages, modify the %packages section of the kickstart file after you save it. Refer to Section 14.5, “Package Selection” for details.

## 15.10. Pre-Installation Script

You can add commands to run on the system immediately after the kickstart file has been parsed and before the installation begins. If you have configured the network in the kickstart file, the network is enabled before this section is processed. To include a pre-installation script, type it in the text area.

Important — anaconda no longer uses busybox

The version of anaconda in previous releases of Fedora included a version of busybox that provided shell commands in the pre-installation and post-installation environments. The version of anaconda in Fedora 14 no longer includes busybox, and uses GNU bash commands instead.

Refer to Appendix G, Alternatives to busybox commands for more information.

To specify a scripting language to use to execute the script, select the Use an interpreter option and enter the interpreter in the text box beside it. For example, /usr/bin/python2.6 can be specified for a Python script. This option corresponds to using %pre --interpreter /usr/bin/python2.6 in your kickstart file.

Only the most commonly used commands are available in the pre-installation environment:

arping, awk, basename, bash, bunzip2, bzcat, cat, chattr, chgrp, chmod, chown, chroot, chvt, clear, cp, cpio, cut, date, dd, df, dirname, dmesg, du, e2fsck, e2label, echo,
Chapter 15. Kickstart Configurator

egrep, eject, env,expr,false,fdisk,fgrep,find,fsck,fsck.ext2,fsck.ext3,ftp,grep,gunzip,gzip,hdparm,head,hostname,hwclock,ifconfig,insmod,ip,ipcalc,kill,killall,less,ln,load_policy/login,losetup,ls,lsattr,lsmod,md5sum,mkdir,mke2fs,mkfs.ext2,mkfs.ext3,mkinitramfs,mkswap,mktemp,modprobe,mount,mt,mv,nslookup,openvt,pidof,ping,ps,pwd,readlink,rm,rmdir,rmmount,route,rpm,sed,sh,sha1sum,sleep,sort,swapoff,swapon,sync,tail,tar,tee,telnet,top,touch,true,tune2fs,umount,uniq,vconfig,vi,wc,wget,xargs,zcat.

**Important**

Do not include the `%pre` command. It is added for you.

**Note**

The pre-installation script is run after the source media is mounted and stage 2 of the bootloader has been loaded. For this reason it is not possible to change the source media in the pre-installation script.

### 15.11. Post-Installation Script

You can also add commands to execute on the system after the installation is completed. If the network is properly configured in the kickstart file, the network is enabled, and the script can include commands to access resources on the network. To include a post-installation script, type it in the text area.

Figure 15.14. Post-Installation Script
**Important — anaconda no longer uses busybox**

The version of `anaconda` in previous releases of Fedora included a version of `busybox` that provided shell commands in the pre-installation and post-installation environments. The version of `anaconda` in Fedora 14 no longer includes `busybox`, and uses GNU `bash` commands instead. Refer to *Appendix G, Alternatives to busybox commands* for more information.

**Important**

Do not include the `%post` command. It is added for you.

For example, to change the message of the day for the newly installed system, add the following command to the `%post` section:

```
echo "Hackers will be punished" > /etc/motd
```

**Note**

More examples can be found in *Section 14.7.1, “Examples”*.

### 15.11.1. Chroot Environment

To run the post-installation script outside of the chroot environment, click the checkbox next to this option on the top of the *Post-installation* window. This is equivalent to using the `--nochroot` option in the `%post` section.

To make changes to the newly installed file system, within the post-installation section, but outside of the chroot environment, you must prepend the directory name with `/mnt/sysimage/`. For example, if you select *Run outside of the chroot environment*, the previous example must be changed to the following:

```
echo "Hackers will be punished" > /mnt/sysimage/etc/motd
```

### 15.11.2. Use an Interpreter

To specify a scripting language to use to execute the script, select the *Use an interpreter* option and enter the interpreter in the text box beside it. For example, `/usr/bin/python2.2` can be specified for a Python script. This option corresponds to using `%post --interpreter /usr/bin/python2.2` in your kickstart file.

### 15.12. Saving the File

To review the contents of the kickstart file after you have finished choosing your kickstart options, select `File => Preview` from the pull-down menu.
To save the kickstart file, click the **Save to File** button in the preview window. To save the file without previewing it, select **File** => **Save File** or press **Ctrl+S**. A dialog box appears. Select where to save the file.

After saving the file, refer to **Section 14.10, “Starting a Kickstart Installation”** for information on how to start the kickstart installation.
Part IV. After installation

This part of the *Fedora Installation Guide* covers finalizing the installation, as well as some installation-related tasks that you might perform at some time in the future. These include:

- using a Fedora installation disk to rescue a damaged system.
- upgrading to a new version of Fedora.
- removing Fedora from your computer.
Firstboot

**Important — Firstboot not available after text-mode installation**

Firstboot is only available on systems after a graphical installation or after a kickstart installation where a desktop and the X window system were installed and graphical login was enabled. If you performed a text-mode installation or a kickstart installation that did not include a desktop and the X window system, the Firstboot configuration tool does not appear.

Firstboot launches the first time that you start a new Fedora system. Use Firstboot to configure the system for use before you log in.

Welcome

There are a few more steps to take before your system is ready to use. The Setup Agent will now guide you through some basic configuration. Please click the "Forward" button in the lower right corner to continue.

Figure 16.1. Firstboot welcome screen

Select **Forward** to start Firstboot.
16.1. License Agreement

This screen displays the overall licensing terms for Fedora. Each software package in Fedora is covered by its own license. All licensing guidelines for Fedora are located at http://fedoraproject.org/wiki/Legal/Licenses.

License Information

Thank you for installing Fedora. Fedora is a compilation of software packages, each under its own license. The compilation is made available under the GNU General Public License version 2. There are no restrictions on using, copying, or modifying this code. However, there are restrictions and obligations that apply to the redistribution of the code, either in its original or a modified form. Among other things, those restrictions/obligations pertain to the licensing of the redistribution, trademark rights, and export control.

If you would like to understand what those restrictions are, please visit http://fedoraproject.org/wik/Legal/Licenses/LicenseAgreement.

Understood, please proceed.

Figure 16.2. Firstboot license screen

If you agree to the terms of the licence, select Yes, I agree to the License Agreement and click Forward.

16.2. Create User

Create a user account for yourself with this screen. Always use this account to log in to your Fedora system, rather than using the root account.
Create User

It is recommended that you create a 'username' for regular (non-administrative) use of your system. To create a system 'username,' please provide the information requested below.

Username: 
Full Name: 
Password: 
Confirm Password: 

If you need to use network authentication, such as Kerberos or NIS, please click the Use Network Login button.

Use Network Login...

Figure 16.3. Firstboot create user screen

Enter a user name and your full name, and then enter your chosen password. Type your password once more in the Confirm Password box to ensure that it is correct.

To configure Fedora to use network services for authentication of user information, click Use Network Login. Refer to Section 16.2.1, “Authentication Configuration” for further details.

Important — Create at least one user account

If you do not create at least one user account in this step, you will not be able to log in to the Fedora graphical environment. If you skipped this step during installation, refer to Section 9.4.2, “Booting into a Graphical Environment”.

Note — Creating Extra User Accounts

To add additional user accounts to your system after the installation is complete, choose System → Administration → Users & Groups.
16.2.1. Authentication Configuration

If you clicked **Use Network Login** on the **Create User** screen, you must now specify how users are to be authenticated on the system. Use the drop-down menu to select from the following types of user database:

- **Local accounts only** (for use when the user database on the network is not accessible)
- **LDAP** (Lightweight Directory Access Protocol)
- **NIS** (Network Information Service)
- **Winbind** (for use with Microsoft Active Directory)

![Authentication Configuration](image)

*Figure 16.4. Firstboot Authentication Configuration screen*

When you select the type of user database appropriate for your network, you must provide additional details relevant to that database type. For example, if you select **LDAP**, you must specify the **base distinguished name** for LDAP searches, and the address of the LDAP server. You must also select an **Authentication Method** relevant to the type of user database that you chose, for example, a Kerberos password, LDAP password, or NIS password.

The **Advanced Options** tab lets you enable other authentication mechanisms, including fingerprint readers, smart cards, and local access control in `/etc/security/access.conf`. 
16.3. Date and Time

Use this screen to adjust the date and time of the system clock. To change these settings after installation, click System → Administration → Date & Time.
Chapter 16. Firstboot

Date and Time

Please set the date and time for the system.

Figure 16.6. Firstboot date and time screen

Click the Synchronize date and time over the network checkbox to configure your system to use Network Time Protocol (NTP) servers to maintain the accuracy of the clock. NTP provides time synchronization service to computers on the same network. Many public NTP servers are available on the Internet.

16.4. Hardware Profile

Firstboot displays a screen that allows you to submit your hardware information anonymously to the Fedora Project. Developers use these hardware details to guide further support efforts. You can read more about this project and its development at http://smolts.org/.
Hardware Profile

Smolt is a hardware profiler for The Fedora Project. Submitting your profile is a great way to give back to the community as this information is used to help focus our efforts on popular hardware and platforms. Submissions are anonymous. Sending your profile will enable a monthly check-in.

Figure 16.7. Firstboot hardware profile screen

To opt in to this important work, select Send Profile. If you choose not to submit any profile data, do not change the default. Select Finish to continue to the login screen.

Update Your System

To ensure the security of your system, run a package update after the installation completes. Chapter 17, Your Next Steps explains how to update your Fedora system.
Your Next Steps

Fedora provides you with a complete operating system with a vast range of capabilities, supported by a large community.

17.1. Updating Your System

The Fedora Project releases updated software packages for Fedora throughout the support period of each version. Updated packages add new features, improve reliability, resolve bugs, or remove security vulnerabilities. To ensure the security of your system, update regularly, and as soon as possible after a security announcement is issued. Refer to Section 17.4, “Subscribing to Fedora Announcements and News” for information on the Fedora announcements services.

An update applet reminds you of updates when they are available. This applet is installed by default in Fedora. It checks for software updates from all configured repositories, and runs as a background service. It generates a notification message on the desktop if updates are found, and you can click the message to update your system’s software.

To update your system with the latest packages manually, use Update System:

1. Choose System → Administration → Update System.
2. To review the list of updated packages, select Review.
3. Click Update System to begin the update process.
4. If one or more updates require a system reboot, the update process displays a dialog with the option to Reboot Now. Either select this option to reboot the system immediately, or Cancel it and reboot the system at a more convenient time.
5. If a reboot is not required the update will conclude with a dialog that indicates that the System Update Completed and all selected updates have been successfully installed as well as a button to Close Update System.

To update packages from the command-line, use the
**Chapter 17. Your Next Steps**

**yum utility.** Type this command to begin a full update of your system with **yum:**

```
    su -c 'yum update'
```

Enter the root password when prompted.

Refer to [http://docs.fedoraproject.org/yum/](http://docs.fedoraproject.org/yum/) for more information on **yum.**

---

**Network Connection Required**

Ensure that your system has an active network connection before you run the **Update Software** tool, or the **yum** utility. The update process downloads information and packages from a network of servers.

---

If your Fedora system has a permanent network connection, you may choose to enable daily system updates. To enable automatic updates, follow the instructions on the webpage [http://docs.fedoraproject.org/yum/sn-updating-your-system.html](http://docs.fedoraproject.org/yum/sn-updating-your-system.html).

---

### 17.2. Finishing an Upgrade

**System Updates Recommended**

Once you have rebooted your system after performing an upgrade, you should also perform a manual system update. Consult *Section 17.1, “ Updating Your System”* for more information.

If you chose to upgrade your system from a previous release rather than perform a fresh installation, you may want to examine the differences in the package set. *Section 8.14.2, “Upgrading Using the Installer”* advised you to create a package listing for your original system. You can now use that listing to determine how to bring your new system close to the original system state.

You can obtain a list of orphaned packages (that is, packages that are no longer in the repositories) from the **package-cleanup** tool. Install the **yum-utils** package and then run **package-cleanup --orphans**. The tool will show you orphaned packages and packages that are partially uninstalled but for which the %postun script failed.

Most software repository configurations are stored in packages that end with the term **release**. Check the old package list for the repositories that were installed:

```
    awk '{print $1}' ~/old-pkglist.txt | grep 'release$'
```

If necessary, retrieve and install these software repository packages from their original sources on the Internet. Follow the instructions at the originating site to install the repository configuration packages for use by **yum** and other software management tools on your Fedora system.

Then run the following commands to make a list of other missing software packages:

```
    awk '{print $1}' ~/old-pkglist.txt | sort | uniq > ~/old-pkgnames.txt
```
### 17.3. Switching to a Graphical Login

#### Important — Access to Software Repositories Might Be Required

To switch to a graphical environment, you might need to install extra software from a repository. You can access Fedora repositories through the Internet or use a Fedora installation CD or DVD as a repository. Refer to Section 17.3.1, “Enabling Access to Software Repositories from the Command Line”.

If you installed using a text login and wish to switch to a graphical login, follow this procedure.

1. If you are not already root, switch users to the root account:

   ```
   su -
   ```

   Provide the administrator password when prompted.

2. If you have not already done so, install the X Window System and a graphical desktop environment. For example, to install the GNOME desktop environment, use this command:

   ```
   yum groupinstall "X Window System" "GNOME Desktop Environment"
   ```

   To install the KDE desktop environment, use:

   ```
   yum groupinstall "X Window System" KDE
   ```

   To install the XFCE desktop environment, use:

   ```
   yum groupinstall "X Window System" XFCE
   ```

   This step may take some time as your Fedora system downloads and installs additional software. You may be asked to provide the installation media depending on your original installation source.

3. Run the following command to edit the `/etc/inittab` file:

   ```
   rpm -qa --qf '%{NAME}\n' | sort | uniq > ~/new-pkgnames.txt
diff -u ~/old-pkgnames.txt ~/new-pkgnames.txt | grep '^-' | sed 's/^\-//' > /tmp/pkgs-to-install.txt
   ```

   Now use the file `/tmp/pkgs-to-install.txt` with the `yum` command to restore most or all of your old software:

   ```
   su -c 'yum install `cat /tmp/pkgs-to-install.txt`'
   ```

#### Missing Software

Due to changes in package complements between Fedora releases, it is possible this method may not restore all the software on your system. You can use the routines above to again compare the software on your system, and remedy any problems you find.
4. Press the **I** key to enter **insert** mode.

5. Find the line that includes the text **initdefault**. Change the numeral **3** to **5**.

6. Type **:wq** and press the **Enter** key to save the file and exit the **vi** text editor.

Reboot the system using the **reboot** command. Your system will restart and present a graphical login.

If you encounter any problems with the graphical login, refer to Chapter 9, Troubleshooting Installation on an Intel or AMD System or consult one of the help sources listed in Section 1.2, “Getting Additional Help”.

### 17.3.1. Enabling Access to Software Repositories from the Command Line

The usual way to install new software on a Fedora system is through a software repository. You can access Fedora repositories through the Internet, or use a Fedora installation CD or DVD as a repository. The software that you access through online repositories is more up-to-date than what is available on an installation CD or DVD. Furthermore, configuring a Fedora system to access online repositories is generally easier than configuring the system to use an installation CD or DVD as a repository, as long as you have an existing, wired network connection available.

#### 17.3.1.1. Enabling Access to Software Repositories Through the Internet

By default, every Fedora installation is already configured to access Fedora repositories through the Internet. Therefore, all you must do is ensure that the system can access the Internet. If you have an existing, wired network connection available, this process is straightforward:

1. If you are not already root, switch users to the **root** account:

   ```
   su -
   ```

2. Ensure that the system is plugged into your network. Note that your network might be as small as two devices — a computer and an external modem/router.

3. Run **system-config-network**. The network configuration tool starts and displays the **Select Action** screen.

4. Select **Edit a device params** and press **Enter**. The network configuration tool displays the **Select A Device** screen with a list of network interfaces present on your system. The first interface is named **eth0** by default.

5. Select a network interface to configure and press **Enter**. The network configuration tool takes you to the **Network Configuration** screen.

6. You can manually configure a static IP, gateway, and DNS servers on this screen or leave these fields blank to accept the default values. When you have chosen a configuration, select **OK**, and press **Enter**. The network configuration tool takes you back to the **Select A Device** screen.

7. Select **Save** and press **Enter**. The network configuration tool takes you back to the **Select Action** screen.
8. Select **Save&Quit** and press **Enter**. The network configuration tool saves your settings and exits.

9. Run **ifup interface**, where *interface* is the network interface that you configured with the network configuration tool. For example, run **ifup eth0** to start eth0.

Configuration of dial-up or wireless Internet connections is more complicated and beyond the scope of this guide.

### 17.3.1.2. Using a Fedora Installation CD or DVD as a Software Repository

You can use a Fedora installation CD or DVD as a software repository, either in the form of a physical disc, or in the form of an ISO image file.

1. If you are using a physical CD or DVD, insert the disc into your computer.

2. If you are not already root, switch users to the root account:

   ```
   su -
   ```

3. Create a *mount point* for the repository:

   ```
   mkdir -p /path/to/repo
   ```

   where */path/to/repo* is a location for the repository, for example, */mnt/repo*

4. **Mount** the CD or DVD on the mount point that you just created. If you are using a physical disc, you need to know the *device name* of your CD or DVD drive. You can find the names of any CD or DVD drives on your system with the command **cat /proc/sys/dev/cdrom/info**. The first CD or DVD drive on the system is typically named *sr0*. When you know the device name, mount the CD or DVD:

   ```
   mount -r -t iso9660 /dev/device_name /path/to/repo
   ```

   For example: **mount -r -t iso9660 /dev/sr0 /mnt/repo**

   If you are using an ISO image file of a disc, mount the image file like this:

   ```
   mount -r -t iso9660 -o loop /path/to/image/file.iso /path/to/repo
   ```

   For example: **mount -r -o loop /home/root/Downloads/Fedora-14-i386-DVD.iso /mnt/repo**

   Note that you can only mount an image file if the storage device that holds the image file is itself mounted. For example, if the image file is stored on a hard drive that it not mounted automatically when the system boots, you must mount the hard drive before you mount an image file stored on that hard drive. Consider a hard drive named */dev/sdb* that is not automatically mounted at boot time and which has an image file stored in a directory named *Downloads* on its first partition:

   ```
   mkdir /mnt/temp
   mount /dev/sdb1 /mnt/temp
   mkdir /mnt/repo
   mount -r -t iso9660 -o loop mount -r -o loop /mnt/temp/Downloads/Fedora-14-i386-DVD.iso /mnt/repo
   ```
If you are not sure whether a storage device is mounted, run the `mount` command to obtain a list of current mounts. If you are not sure of the device name or partition number of a storage device, run `fdisk -l` and try to identify it in the output.

5. Edit the `/etc/yum.repos.d/fedora.repo` and `/etc/yum.repos.d/fedora-updates.repo` files to use the new repository. In each case:

   1. Open the file with the `vi` text editor. For example:

   ```
   vi /etc/yum.repos.d/fedora.repo
   ```

   2. Press the `I` key to enter `insert` mode.

   3. Type a `#` character at the start of any line in the file that starts with `baseurl` or `mirrorlist`. The `#` character comments out the line so that the package management software ignores it.

   4. Find the `[fedora]` section of the `fedora.repo` file or the `[updates]` section of the `fedora-updates.repo` file. Note that this section includes a line that now starts `# baseurl` that you previously commented out.

   5. Insert a new line after the line that starts `# baseurl`:

   ```
   baseurl=file://path/to/repo
   ```

   For example, `baseurl=file:///mnt/repo`

   6. Press the `Esc` key to exit `insert` mode.

   7. Type `:wq` and press the `Enter` key to save the file and exit the `vi` text editor.

   8. After installing or upgrading software from the CD or DVD, edit the `/etc/yum.repos.d/fedora.repo` and `/etc/yum.repos.d/fedora-updates.repo` files again to undo the changes that you made.

### 17.4. Subscribing to Fedora Announcements and News

To receive information about package updates, subscribe to either the announcements mailing list, or the RSS feeds.

Fedora Project announcements mailing list

https://www.redhat.com/mailman/listinfo/fedora-announce-list

Fedora Project RSS feeds

http://fedoraproject.org/infofeed/

The announcements mailing list also provides you with news on the Fedora Project, and the Fedora community.

**Security Announcements**

Announcements with the keyword `[SECURITY]` in the title identify package updates that resolve security vulnerabilities.
17.5. Finding Documentation and Support

Members of the Fedora community provide support through mailing lists, Web forums and Linux User Groups (LUGs) across the world.

The Web site for the formally endorsed forums is http://forums.fedoraforum.org/.

The following resources provide information on many aspects of Fedora:

• The FAQ on the Fedora Project website
  http://fedoraproject.org/wiki/FAQ/

• The documents available from the Fedora Documentation Project Web site
  http://docs.fedoraproject.org/

• The Linux Documentation Project (LDP)
  http://www.tldp.org/

• The Red Hat Enterprise Linux documentation, much of which also applies to Fedora
  http://www.redhat.com/docs/manuals/enterprise/

Many other organizations and individuals also provide tutorials and HOWTOs for Fedora on their Web sites. You can locate information on any topic by using Google’s Linux search site, located at http://www.google.com/linux.

17.6. Joining the Fedora Community

The Fedora Project is driven by the individuals that contribute to it. Community members provide support and documentation to other users, help to improve the software included in Fedora by testing, and develop new software alongside the programmers employed by Red Hat. The results of this work are available to all.

To make a difference, start here:

http://join.fedoraproject.org/
Basic System Recovery

When things go wrong, there are ways to fix problems. However, these methods require that you understand the system well. This chapter describes how to boot into rescue mode, single-user mode, and emergency mode, where you can use your own knowledge to repair the system.

18.1. Rescue Mode

18.1.1. Common Problems
You might need to boot into one of these recovery modes for any of the following reasons:

• You are unable to boot normally into Fedora (runlevel 3 or 5).

• You are having hardware or software problems, and you want to get a few important files off of your system's hard drive.

• You forgot the root password.

18.1.1.1. Unable to Boot into Fedora
This problem is often caused by the installation of another operating system after you have installed Fedora. Some other operating systems assume that you have no other operating system(s) on your computer. They overwrite the Master Boot Record (MBR) that originally contained the GRUB boot loader. If the boot loader is overwritten in this manner, you cannot boot Fedora unless you can get into rescue mode and reconfigure the boot loader.

Another common problem occurs when using a partitioning tool to resize a partition or create a new partition from free space after installation, and it changes the order of your partitions. If the partition number of your / partition changes, the boot loader might not be able to find it to mount the partition. To fix this problem, boot in rescue mode and modify the /boot/grub/grub.conf file.

For instructions on how to reinstall the GRUB boot loader from a rescue environment, refer to Section 18.1.2.1, "Reinstalling the Boot Loader".

18.1.1.2. Hardware/Software Problems
This category includes a wide variety of different situations. Two examples include failing hard drives and specifying an invalid root device or kernel in the boot loader configuration file. If either of these occur, you might not be able to reboot into Fedora. However, if you boot into one of the system recovery modes, you might be able to resolve the problem or at least get copies of your most important files.

18.1.1.3. Root Password
What can you do if you forget your root password? To reset it to a different password, boot into rescue mode or single-user mode, and use the passwd command to reset the root password.

18.1.2. Booting into Rescue Mode
Rescue mode provides the ability to boot a small Fedora environment entirely from CD-ROM, or some other boot method, instead of the system's hard drive.
As the name implies, rescue mode is provided to rescue you from something. During normal operation, your Fedora system uses files located on your system's hard drive to do everything — run programs, store your files, and more.

However, there may be times when you are unable to get Fedora running completely enough to access files on your system's hard drive. Using rescue mode, you can access the files stored on your system's hard drive, even if you cannot actually run Fedora from that hard drive.

To boot into rescue mode, you must be able to boot the system using one of the following methods:

- By booting the system from a boot CD-ROM or DVD.
- By booting the system from other installation boot media, such as USB flash devices.
- By booting the system from the Fedora installation DVD.

Once you have booted using one of the described methods, add the keyword `rescue` as a kernel parameter. For example, for an x86 system, type the following command at the installation boot prompt:

```
linux rescue
```

You are prompted to answer a few basic questions, including which language to use. It also prompts you to select where a valid rescue image is located. Select from Local CD-ROM, Hard Drive, NFS image, FTP, or HTTP. The location selected must contain a valid installation tree, and the installation tree must be for the same version of Fedora as the Fedora disk from which you booted. If you used a boot CD-ROM or other media to start rescue mode, the installation tree must be from the same tree from which the media was created. For more information about how to setup an installation tree on a hard drive, NFS server, FTP server, or HTTP server, refer to the earlier section of this guide.

If you select a rescue image that does not require a network connection, you are asked whether or not you want to establish a network connection. A network connection is useful if you need to backup files to a different computer or install some RPM packages from a shared network location, for example.

The following message is displayed:

```
The rescue environment will now attempt to find your Linux installation and mount it under the directory /mnt/sysimage. You can then make any changes required to your system. If you want to proceed with this step choose 'Continue'. You can also choose to mount your file systems read-only instead of read-write by choosing 'Read-only'. If for some reason this process fails you can choose 'Skip' and this step will be skipped and you will go directly to a command shell.
```

If you select Continue, it attempts to mount your file system under the directory `/mnt/sysimage/`. If it fails to mount a partition, it notifies you. If you select Read-Only, it attempts to mount your file system under the directory `/mnt/sysimage/`, but in read-only mode. If you select Skip, your file system is not mounted. Choose Skip if you think your file system is corrupted.

Once you have your system in rescue mode, a prompt appears on VC (virtual console) 1 and VC 2 (use the Ctrl-Alt-F1 key combination to access VC 1 and Ctrl-Alt-F2 to access VC 2):

Refer to the earlier sections of this guide for more details.
Booting into Rescue Mode

If you selected **Continue** to mount your partitions automatically and they were mounted successfully, you are in single-user mode.

Even if your file system is mounted, the default root partition while in rescue mode is a temporary root partition, not the root partition of the file system used during normal user mode (runlevel 3 or 5). If you selected to mount your file system and it mounted successfully, you can change the root partition of the rescue mode environment to the root partition of your file system by executing the following command:

```
chroot /mnt/sysimage
```

This is useful if you need to run commands such as **rpm** that require your root partition to be mounted as `/`. To exit the **chroot** environment, type **exit** to return to the prompt.

If you selected **Skip**, you can still try to mount a partition or LVM2 logical volume manually inside rescue mode by creating a directory such as `/foo`, and typing the following command:

```
mount -t ext4 /dev/mapper/VolGroup00-LogVol02 /foo
```

In the above command, `/foo` is a directory that you have created and `/dev/mapper/VolGroup00-LogVol02` is the LVM2 logical volume you want to mount. If the partition is of type **ext2** or **ext3** replace **ext4** with **ext2** or **ext3** respectively.

If you do not know the names of all physical partitions, use the following command to list them:

```
fdisk -l
```

If you do not know the names of all LVM2 physical volumes, volume groups, or logical volumes, use the following commands to list them:

```
pvdisplay
```
```
vgdisplay
```
```
lvdisplay
```

From the prompt, you can run many useful commands, such as:

- **ssh**, **scp**, and **ping** if the network is started
- **dump** and **restore** for users with tape drives
- **parted** and **fdisk** for managing partitions
- **rpm** for installing or upgrading software
- **joe** for editing configuration files
Chapter 18. Basic System Recovery

18.1.2.1. Reinstalling the Boot Loader
In many cases, the GRUB boot loader can mistakenly be deleted, corrupted, or replaced by other operating systems.

The following steps detail the process on how GRUB is reinstalled on the master boot record:

• Boot the system from an installation boot medium.
• Type `linux rescue` at the installation boot prompt to enter the rescue environment.
• Type `chroot /mnt/sysimage` to mount the root partition.
• Type `sbin/grub-install bootpart` to reinstall the GRUB boot loader, where `bootpart` is the boot partition (typically, `/dev/sda`).
• Review the `/boot/grub/grub.conf` file, as additional entries may be needed for GRUB to control additional operating systems.
• Reboot the system.

18.1.3. Booting into Single-User Mode
One of the advantages of single-user mode is that you do not need a boot CD-ROM; however, it does not give you the option to mount the file systems as read-only or not mount them at all.

If your system boots, but does not allow you to log in when it has completed booting, try single-user mode.

In single-user mode, your computer boots to runlevel 1. Your local file systems are mounted, but your network is not activated. You have a usable system maintenance shell. Unlike rescue mode, single-user mode automatically tries to mount your file system. Do not use single-user mode if your file system cannot be mounted successfully. You cannot use single-user mode if the runlevel 1 configuration on your system is corrupted.

On an x86 system using GRUB, use the following steps to boot into single-user mode:

1. At the GRUB splash screen at boot time, press any key to enter the GRUB interactive menu.
2. Select Fedora with the version of the kernel that you wish to boot and type `a` to append the line.
3. Go to the end of the line and type `single` as a separate word (press the Spacebar and then type `single`). Press Enter to exit edit mode.

18.1.4. Booting into Emergency Mode
In emergency mode, you are booted into the most minimal environment possible. The root file system is mounted read-only and almost nothing is set up. The main advantage of emergency mode over single-user mode is that the init files are not loaded. If init is corrupted or not working, you can still mount file systems to recover data that could be lost during a re-installation.
To boot into emergency mode, use the same method as described for single-user mode in Section 18.1.3, “Booting into Single-User Mode” with one exception, replace the keyword `single` with the keyword `emergency`. 
Chapter 19.

Upgrading Your Current System
This chapter explains the various methods available for upgrading your Fedora system.

19.1. Determining Whether to Upgrade or Re-Install
While upgrading from Fedora 13 is supported, you are more likely to have a consistent experience by backing up your data and then installing this release of Fedora 14 over your previous Fedora installation.

To upgrade from Fedora 13 you should bring your system up to date before performing the upgrade.

*This recommended reinstallation method helps to ensure the best system stability possible.*

If you currently use Fedora 13, you can perform a traditional, installation program-based upgrade.

However, before you chose to upgrade your system, there are a few things you should keep in mind:

- Individual package configuration files may or may not work after performing an upgrade due to changes in various configuration file formats or layouts.
- If you have one of Red Hat’s layered products (such as the Cluster Suite) installed, it may need to be manually upgraded after the upgrade has been completed.
- Third party or ISV applications may not work correctly following the upgrade.

Upgrading your system installs updated versions of the packages which are currently installed on your system.

The upgrade process preserves existing configuration files by renaming them with an `.rpmsave` extension (for example, `sendmail.cf.rpmsave`). The upgrade process also creates a log of its actions in `/root/upgrade.log`.

**Warning**

As software evolves, configuration file formats can change. It is very important to carefully compare your original configuration files to the new files before integrating your changes.

**Note**

It is always a good idea to back up any data that you have on your systems. For example, if you are upgrading or creating a dual-boot system, you should back up any data you wish to keep on your hard drive(s). Mistakes do happen and can result in the loss of all of your data.

Some upgraded packages may require the installation of other packages for proper operation. If you choose to customize your packages to upgrade, you may be required to resolve dependency problems. Otherwise, the upgrade procedure takes care of these dependencies, but it may need to install additional packages which are not on your system.

Depending on how you have partitioned your system, the upgrade program may prompt you to add an additional swap file. If the upgrade program does not detect a swap file that equals twice your RAM, it asks you if you would like to add a new swap file. If your system does not have a lot of RAM (less than 256 MB), it is recommended that you add this swap file.
19.2. Upgrading Your System

In most cases, the simplest way to upgrade an existing Fedora installation is with the `preupgrade` tool. When a new version of Fedora is available, `preupgrade` downloads the packages necessary to upgrade your installation, and initiates the upgrade process.

Install `preupgrade` with your graphical package manager, or type `yum install preupgrade` at the command line and press Enter.

To run `preupgrade`, type `preupgrade` at the command line and press Enter.

You can also upgrade a Fedora installation by starting the installation process by any of the methods described in Chapter 8, Installing using anaconda. If the installer detects a previous Fedora installation on the system, it will ask you whether you want to upgrade that installation — refer to Section 8.14.1, "The Upgrade Dialog"

The Upgrade Examine screen appears if you have instructed the installation program to perform an upgrade.

**Note**

If the contents of your `/etc/fedora-release` file have been changed from the default, your Fedora installation may not be found when attempting an upgrade to Fedora 14.

You can relax some of the checks against this file by booting with the following boot command:

```
linux upgradeany
```

Use the `linux upgradeany` command if your Fedora installation was not given as an option to upgrade.

To perform an upgrade, select **Perform an upgrade of an existing installation**. Click Next when you are ready to begin your upgrade.

To re-install your system, select **Perform a new Fedora installation** and refer to Chapter 8, Installing using anaconda for further instructions.
Removing Fedora

We respect your freedom to choose an operating system for your computer. This section explains how to uninstall Fedora.

⚠️ These instructions may destroy data!

If you have data from Fedora that you want to keep, back it up before you proceed. Write your data to CD, DVD, external hard disk, or other storage device.

As a precaution, also back up data from any other operating systems that are installed on the same computer. Mistakes do happen and can result in the loss of all your data.

If you back up data from Fedora to be used later in another operating system, make sure that the storage medium or device is readable by that other operating system. For example, without extra third-party software, Microsoft Windows cannot read an external hard drive that you have formatted with Fedora to use the ext2, ext3, or ext4 file system.

To uninstall Fedora from your x86-based system, you must remove the Fedora boot loader information from your master boot record (MBR) and remove any partitions that contain the operating system. The method for removing Fedora from your computer varies, depending on whether Fedora is the only operating system installed on the computer, or whether the computer is configured to dual-boot Fedora and another operating system.

These instructions cannot cover every possible computer configuration. If your computer is configured to boot three or more operating systems, or has a highly-customized partition scheme, use the following sections as a general guide to partition removal with the various tools described. In these situations, you will also need to learn to configure your chosen bootloader. See Appendix E, The GRUB Boot Loader for a general introduction to the subject, but detailed instructions are beyond the scope of this document.

Legacy versions of Microsoft operating systems

**Fdisk**, the disk partitioning tool provided with MS-DOS and Microsoft Windows, is unable to remove the file systems used by Fedora. MS-DOS and versions of Windows prior to Windows XP (except for Windows 2000) have no other means of removing or modifying partitions. Refer to Section 20.3, “Replacing Fedora with MS-DOS or legacy versions of Microsoft Windows” for alternative removal methods for use with MS-DOS and these versions of Windows.

20.1. Fedora is the only operating system on the computer

If Fedora is the only operating system on your computer, use the installation media for the replacement operating system to remove Fedora. Examples of installation media include the Windows XP installation CD, Windows Vista installation DVD, Mac OS X installation CDs or DVD, or the installation CD, CDs, or DVD of another Linux distribution.

Note that some manufacturers of factory-built computers pre-installed with Microsoft Windows do not supply the Windows installation CD or DVD with the computer. The manufacturer may instead have supplied their own “system restore disk”, or have included software with the computer that allowed you to create your own “system restore disk” when you first started the computer. In some cases, the system restore software is stored on a separate partition on the system’s hard drive. If you cannot...
identify the installation media for an operating system that was pre-installed on your computer, consult the documentation supplied with the machine, or contact the manufacturer.

When you have located the installation media for your chosen operating system:

1. Back up any data that you want to keep.
2. Shut down the computer.
3. Boot your computer with the installation disk for the replacement operating system.
4. Follow the prompts presented during the installation process. Windows, OS X, and most Linux installation disks allow you to manually partition your hard drive during the installation process, or will offer you the option to remove all partitions and start with a fresh partition scheme. At this point, remove any existing partitions that the installation software detects or allow the installer to remove the partitions automatically. "System restore" media for computers pre-installed with Microsoft Windows might create a default partition layout automatically without input from you.

**Warning**

If your computer has system restore software stored on a partition on a hard drive, take care when removing partitions while installing an operating system from other media. Under these circumstances, you could destroy the partition holding the system restore software.

### 20.2. Your computer dual-boots Fedora and another operating system

If your computer is configured to dual-boot Fedora and another operating system, removing Fedora without removing the partitions containing the other operating system and its data is more complicated. Specific instructions for a number of operating systems are set out below. To keep neither Fedora nor the other operating system, follow the steps described for a computer with only Fedora installed: [Section 20.1, “Fedora is the only operating system on the computer”](#)
20.2.1. Your computer dual-boots Fedora and a Microsoft Windows operating system

**Warning**

Once you commence this process, your computer may be left in an unbootable state until you complete the entire set of instructions. Carefully read the steps below before beginning the removal process. Consider opening these instructions on another computer or printing them so that you have access to them at all times during the process.

This procedure relies on the **Windows Recovery Console** that loads from the Windows installation disk, so you will not be able to complete the procedure without access to this disk. If you start this procedure and do not complete it, you could leave your computer in a condition where you cannot boot it. The "system restore disk" supplied with some factory-built computers that are sold with Windows pre-installed on them might not include the **Windows Recovery Console**.

During the process outlined in these instructions, the **Windows Recovery Console** will prompt you for the Administrator password for your Windows system. Do not follow these instructions unless you know the Administrator password for your system or are certain that an Administrator password has never been created, even by the computer manufacturer.

1. Remove the Fedora partitions
   a. Boot your computer into your Microsoft Windows environment.
   b. Click **Start>Run...**, type `diskmgmt.msc` and press **Enter**. The **Disk Management** tool opens.
      
      The tool displays a graphical representation of your disk, with bars representing each partition. The first partition is usually labeled **NTFS** and corresponds to your **C:** drive. At least two Fedora partitions will be visible. Windows will not display a file system type for these partitions, but may allocate drive letters to some of them.
   c. Right-click on one of the Fedora partitions, then click **Delete Partition** and click **Yes** to confirm the deletion. Repeat this process for the other Fedora partitions on your system. As you delete partitions, Windows labels the space on the hard drive previously occupied by those partitions as **unallocated**.

2. Enable Windows to use the space on your hard drive vacated by Fedora (optional)

**Note**

This step is not required to remove Fedora from your computer. However, if you skip this step, you will leave part of your hard drive’s storage capacity unusable by Windows. Depending on your configuration, this might be a significant portion of the storage capacity of the drive.
Chapter 20. Removing Fedora

Decide whether to extend an existing Windows partition to use the extra space, or create a new Windows partition in that space. If you create new a Windows partition, Windows will allocate a new drive letter to it and will interact with it as if it is a separate hard drive.

### Extending an existing Windows partition

**Note**

The diskpart tool used in this step is installed as part of the Windows XP and Windows 2003 operating systems. If you are performing this step on a computer running Windows 2000 or Windows Server 2000, you can download a version of diskpart for your operating system from the Microsoft website.

**a.** Click Start>Run..., type diskpart and press Enter. A command window appears.

**b.** Type list volume and press Enter. Diskpart displays a list of the partitions on your system with a volume number, its drive letter, volume label, filesystem type, and size. Identify the Windows partition that you would like to use to occupy the space vacated on your hard drive by Fedora and take note of its volume number (for example, your Windows C: drive might be "Volume 0").

**c.** Type select volume N (where N is the volume number for the Windows partition that you want to extend) and press Enter. Now type extend and press Enter. Diskpart now extends your chosen partition to fill the remaining space on your hard drive. It will notify you when the operation is complete.

### Adding a new Windows partition

**a.** In the Disk Management window, right-click on disk space that Windows labels as unallocated and select New Partition from the menu. The New Partition Wizard starts.

**b.** Follow the prompts presented by the New Partition Wizard. If you accept the default options, the tool will create a new partition that fills all available space on the hard drive, assigns it the next available drive letter, and formats it with the NTFS file system.

### 3. Restore the Windows bootloader

**a.** Insert the Windows installation disk and restart your computer. As your computer starts, the following message will appear on the screen for a few seconds:

```
Press any key to boot from CD
```

Press any key while the message is still showing and the Windows installation software will load.

**b.** When the Welcome to Setup screen appears, you can start the Windows Recovery Console. The procedure is slightly different on different versions of Windows:

- On Windows 2000 and Windows Server 2000, press the R key, then the C key.

**c.** The Windows Recovery Console scans your hard drives for Windows installations, and assigns a number to each one. It displays a list of Windows installations and prompts you
Your computer dual-boots Fedora and a Microsoft Windows operating system

to select one. Type the number corresponding to the Windows installation that you want to restore.

d. The **Windows Recovery Console** prompts you for the Administrator password for your Windows installation. Type the Administrator password and press the **Enter** key. If there is no administrator password for this system, press only the **Enter** key.

e. At the prompt, type the command `fixmbr` and press the **Enter**. The `fixmbr` tool now restores the Master Boot Record for the system.

f. When the prompt reappears, type `exit` and press the **Enter** key.

g. Your computer will restart and boot your Windows operating system.

### 20.2.1.2. Windows Vista and Windows Server 2008

**Warning**

Once you commence this process, your computer may be left in an unbootable state until you complete the entire set of instructions. Carefully read the steps below before beginning the removal process. Consider opening these instructions on another computer or printing them so that you have access to them at all times during the process.

This procedure relies on the **Windows Recovery Environment** that loads from the Windows installation disk and you will not be able to complete the procedure without access to this disk. If you start this procedure and do not complete it, you could leave your computer in a condition where you cannot boot it. The "system restore disk" supplied with some factory-built computers that are sold with Windows pre-installed on them might not include the **Windows Recovery Environment**.

1. Remove the Fedora partitions
   a. Boot your computer into your Microsoft Windows environment.
   b. Click **Start** then type `diskmgmt.msc` into the **Start Search** box and press **Enter**. The **Disk Management** tool opens.

   The tool displays a graphical representation of your disk, with bars representing each partition. The first partition is usually labeled **NTFS** and corresponds to your **C:** drive. At least two Fedora partitions will be visible. Windows will not display a file system type for these partitions, but may allocate drive letters to some of them.

   c. Right-click on one of the Fedora partitions, then click **Delete Partition** and click **Yes** to confirm the deletion. Repeat this process for the other Fedora partitions on your system. As you delete partitions, Windows labels the space on the hard drive previously occupied by those partitions as **unallocated**.

2. Enable Windows to use the space on your hard drive vacated by Fedora (optional)
Chapter 20. Removing Fedora

Note

This step is not required to remove Fedora from your computer. However, if you skip this step, you will leave part of your hard drive’s storage capacity unusable by Windows. Depending on your configuration, this might be a significant portion of the storage capacity of the drive.

Decide whether to extend an existing Windows partition to use the extra space, or create a new Windows partition in that space. If you create new a Windows partition, Windows will allocate a new drive letter to it and will interact with it as if it is a separate hard drive.

Extending an existing Windows partition

a. In the Disk Management window, right-click on the Windows partition that you want to extend and select Extend Volume from the menu. The Extend Volume Wizard opens.

b. Follow the prompts presented by the Extend Volume Wizard. If you accept the defaults that it offers you, the tool will extend the selected volume to fill all available space on the hard drive.

Adding a new Windows partition

a. In the Disk Management window, right-click on disk space that Windows labels as unallocated and select New Simple Volume from the menu. The New Simple Volume Wizard starts.

b. Follow the prompts presented by the New Simple Volume Wizard. If you accept the default options, the tool will create a new partition that fills all available space on the hard drive, assigns it the next available drive letter, and formats it with the NTFS file system.

3. Restore the Windows bootloader

a. Insert the Windows installation disk and restart your computer. As your computer starts, the following message will appear on the screen for a few seconds:

   Press any key to boot from CD or DVD

   Press any key while the message is still showing and the Windows installation software will load.

b. In the Install Windows dialog, select a language, time and currency format, and keyboard type. Click Next

c. Click Repair your computer.

d. The Windows Recovery Environment (WRE) shows you the Windows installations that it can detect on your system. Select the installation that you want to restore, then click Next.

e. Click Command prompt. A command window will open.

f. Type bootrec /fixmbr and press Enter.

g. When the prompt reappears, close the command window, then click Restart.

h. Your computer will restart and boot your Windows operating system.
20.2.2. Your computer dual-boots Fedora and Mac OS X

The procedure to remove Fedora from a system that dual-boots Fedora and Mac OS X varies depending on whether you have installed Boot Camp on your computer:

You are not using Boot Camp on your computer
1. Open the Disk Utility in /Applications/Utilities.
2. Select the entry on the left for the disk volume containing Fedora.
3. Click the Partition tab on the right side of the dialog.
4. Select the Fedora partitions and click the minus button below the partition layout diagram.
5. Resize your OS X partition to include the newly freed space.

You are using Boot Camp on your computer
1. Open the Boot Camp Assistant in /Applications/Utilities.
2. Select Create or remove a Windows partition and click Next.
3. If your computer has a single internal disk, click Restore.
4. If your computer has multiple internal disks, select the Linux disk, and then select Restore to a single Mac OS partition. Click Continue.

20.2.3. Your computer dual-boots Fedora and a different Linux distribution

Note

Because of the differences between the many different Linux distributions, these instructions are a general guide only. Specific details will vary according to your chosen distribution and the configuration of your particular computer. This example uses GParted as a partition editor and gedit as a text editor, but many other tools are available to perform these tasks. To follow these instructions exactly as written, install GParted and gedit.

1. Remove Fedora partitions
   a. Boot the Linux version that you want to keep on your computer.
   b. Open GParted, either from a desktop menu or by typing gparted at the command line and pressing Enter.
   c. GParted displays the partitions that it detects on your computer, both as a graph and as a table.

      Right-click the Fedora partitions, then select Delete.
2. Remove Fedora entries from your bootloader

Example only

These instructions assume that your system uses the GRUB bootloader. If you use a different bootloader (such as LILO) consult the documentation for that software to identify and remove Fedora entries from its list of boot targets and to ensure that your default operating system is correctly specified.

a. At the command line, type `su -` and press Enter. When the system prompts you for the root password, type the password and press Enter.

b. Type `gedit /boot/grub/grub.conf` and press Enter. This opens the `grub.conf` file in the `gedit` text editor.

c. A typical Fedora entry in the `grub.conf` file consists of four lines:

```
Example 20.1. Example Fedora entry in grub.conf

title Fedora (2.6.27.19-170.2.35.fc10.i686)
root (hd0,1)

kernel /vmlinuz-2.6.27.19-170.2.35.fc10.i686 ro root=UUID=04a07c13-e6bf-6d5a-b207-002689545705 rhgb quiet

initrd /initrd-2.6.27.19-170.2.35.fc10.i686.img
```

Depending on the configuration of your system, there may be multiple Fedora entries in `grub.conf`, each corresponding to a different version of the Linux kernel. Delete each of the Fedora entries from the file.

d. `grub.conf` contains a line that specifies the default operating system to boot, in the format `default=N` where `N` is a number equal to or greater than 0. If `N` is set to 0, GRUB will boot the first operating system in the list. If `N` is set to 1, it will boot the second operating system, and so forth.

Identify the entry for the operating system that you want GRUB to boot by default and note its place in the order within the list.

Make sure that the `default=` line contains the number one below the number of your chosen default operating system in the list.

Save the updated `grub.conf` file and close `gedit`
3. **Make space available to your operating system**

   **Note**

   This step is not required to remove Fedora from your computer. However, if you skip this step, you will leave part of your hard drive's storage capacity unusable by your other Linux operating system. Depending on your configuration, this might be a significant portion of the storage capacity of the drive.

   **Note**

   To carry out this step, you require live media for a Linux distribution, for example, the Fedora Live CD or the Knoppix DVD.

   The method to make the space freed by removing the Fedora partitions available to your other Linux operating system differs, depending on whether your chosen operating system is installed on disk partitions configured to use Logical Volume Management (LVM) or not.

   - **If you do not use LVM**
     a. Boot your computer from Linux live media, and install `gparted` if it is not already present.
     b. Open **GParted**, either from a desktop menu or by typing `gparted` at the command line and pressing **Enter**.
     c. **GParted** displays the partitions on your system both as a graph and as a table. Click on the partition that you want to extend to use the space freed by removing Fedora, and click the **Resize/Move** button.
     d. A new dialog opens, allowing you to specify a new size for the partition by entering it as numbers, or by dragging the sides of the graphical representation of the partition so that it fills the available space. Click the **Resize/Move** button in this dialog to confirm your choice.
     e. Back in the main **GParted** window, click **Apply**. Take note of the name of the partition that you just resized, for example, `/dev/sda3`.
     f. When **GParted** finishes resizing the partition, type `e2fsck partition` at a command line and press **Enter**, where `partition` is the partition that you just resized. For example, if you just resized `/dev/sda3`, you would type `e2fsck /dev/sda3`.

       Linux now checks the file system of the newly-resized partition.
     g. When the file system check finishes, type `resize2fs partition` at a command line and press **Enter**, where `partition` is the partition that you just resized. For example, if you just resized `/dev/sda3`, you would type `resize2fs /dev/sda3`.

       Linux now resizes your file system to fill the newly-resized partition.
     h. Restart your computer. The extra space is now available to your Linux installation.

   - **If you use LVM**
     a. Boot your computer from Linux live media and install `gparted` and `lvm2` if they are not already present.
b. Create a new partition in the free space on the disk
   i. Open **GParted**, either from a desktop menu or by typing `gparted` at the command line and pressing **Enter**.

   ii. **GParted** displays the partitions on your system both as a graph and as a table. The space freed by removing Fedora is labeled **unallocated**. Right-click on the unallocated space and select **New**. Accept the defaults and **GParted** will create a new partition that fills the space available on the drive.

   iii. Click **Apply**. **GParted** writes the changes to your hard drive. Take note of the name of the partition that you just created, and the name of the device that holds the partition. For example, you may have created `/dev/sda3` on device `/dev/sda`.

c. Change the partition type identifier
   i. **Fdisk** is a partitioning tool capable of preparing partitions for LVM. At a command line, type `fdisk device` and press **Enter**, where `device` is the name of the device on which you just created a partition. For example, `fdisk /dev/sda`.

   ii. At the prompt **Command (m for help):**, press **T** and **Enter** to use **fdisk** to change a partition type.

   iii. At the prompt **Partition number (1-4):**, type the number of the partition that you just created. For example, if you just created partition `/dev/sda3`, type the number 3 and press **Enter**. This identifies the partition whose type **fdisk** will change.

   iv. At the prompt **Hex code (type L to list codes):**, type the code `8e` and press **Enter**. This is the code for a Linux LVM partition.

   v. At the prompt **Command (m for help):**, press **W** and **Enter**. **Fdisk** writes the new type code to the partition and exits.

d. Expand the volume group
   i. At the command prompt, type `lvmd` and press **Enter** to start the **lvmd2** tool.

   ii. At the `lvmd>` prompt, type `pvcreate partition` and press **Enter**, where `partition` is the partition that you recently created. For example, `pvcreate /dev/sda3`. This creates `/dev/sda3` as a physical volume in LVM.

   iii. At the `lvmd>` prompt, type `vgextend VolumeGroup partition` and press **Enter**, where `VolumeGroup` is the LVM volume group on which Linux is installed and `partition` is the partition that you recently created. For example, if Linux is installed on `/dev/VolGroup00`, you would type `vgextend /dev/VolGroup00 /dev/sda3` to extend that volume group to include the physical volume at `/dev/sda3`.

   iv. At the `lvmd>` prompt, type `lvextend -l +100%FREE LogVol` and press **Enter**, where `LogVol` is the logical volume that contains your Linux filesystem. For example, to extend `LogVol00` to fill the newly-available space in its volume group, `VolGroup00`, type `lvextend -l +100%FREE /dev/VolGroup00/LogVol00`.

   v. At the `lvmd>` prompt, type `exit` and press **Enter** to exit **lvmd2**

e. Type `e2fsck LogVol` at the command line and press **Enter**, where `LogVol` is the logical volume that you just resized. For example, if you just resized `/dev/VolGroup00/LogVol00`, you would type `e2fsck /dev/VolGroup00/LogVol00`.

Linux now checks the file system of the newly-resized logical volume.
f. When the file system check finishes, type `resize2fs LogVol` at a command line and press Enter, where LogVol is the partition that you just resized. For example, if you just resized `/dev/VolumeGroup00/LogVol00`, you would type `resize2fs /dev/VolumeGroup00/LogVol00`.

Linux now resizes your file system to fill the newly-resized logical volume.

g. Restart your computer. The extra space is now available to your Linux installation.

20.3. Replacing Fedora with MS-DOS or legacy versions of Microsoft Windows

In DOS and Windows, use the Windows `fdisk` utility to create a new MBR with the *undocumented* flag `/mbr`. This ONLY rewrites the MBR to boot the primary DOS partition. The command should look like the following:

```
fdisk /mbr
```

If you need to remove Linux from a hard drive and have attempted to do this with the default DOS (Windows) `fdisk`, you will experience the *Partitions exist but they do not exist* problem. The best way to remove non-DOS partitions is with a tool that understands partitions other than DOS.

To begin, insert the Fedora CD #1 and boot your system. Once you have booted off the CD, a boot prompt appears. At the boot prompt, type: `linux rescue`. This starts the rescue mode program.

You are prompted for your keyboard and language requirements. Enter these values as you would during the installation of Fedora.

Next, a screen appears telling you that the program attempts to find a Fedora install to rescue. Select Skip on this screen.

After selecting Skip, you are given a command prompt where you can access the partitions you would like to remove.

First, type the command `list-harddrives`. This command lists all hard drives on your system that are recognizable by the installation program, as well as their sizes in megabytes.

![Warning]

Be careful to remove only the necessary Fedora partitions. Removing other partitions could result in data loss or a corrupted system environment.

To remove partitions, use the partitioning utility `parted`. Start `parted`, where `/dev/hda` is the device on which to remove the partition:

```
parted /dev/hda
```

Using the `print` command, view the current partition table to determine the minor number of the partition to remove:

```
print
```
The `print` command also displays the partition's type (such as linux-swap, ext2, ext3, ext4 and so on). Knowing the type of the partition helps you in determining whether to remove the partition.

Remove the partition with the command `rm`. For example, to remove the partition with minor number 3:

```
rm 3
```

**Important**

The changes start taking place as soon as you press [Enter], so review the command before committing to it.

After removing the partition, use the `print` command to confirm that it is removed from the partition table.

Once you have removed the Linux partitions and made all of the changes you need to make, type `quit` to quit `parted`.

After quitting `parted`, type `exit` at the boot prompt to exit rescue mode and reboot your system, instead of continuing with the installation. The system should reboot automatically. If it does not, you can reboot your computer using `Control+Alt+Delete`.
Part V. Technical appendixes

The appendixes in this section do not contain instructions that tell you how to install Fedora. Instead, they provide technical background that you might find helpful to understand the options that Fedora offers you at various points in the installation process.
Appendix A. An Introduction to Disk Partitions

This appendix is not necessarily applicable to non-x86-based architectures. However, the general concepts mentioned here may apply.

If you are reasonably comfortable with disk partitions, you could skip ahead to Section A.1.4, “Making Room For Fedora”, for more information on the process of freeing up disk space to prepare for a Fedora installation. This section also discusses the partition naming scheme used by Linux systems, sharing disk space with other operating systems, and related topics.

A.1. Hard Disk Basic Concepts

Hard disks perform a very simple function — they store data and reliably retrieve it on command.

When discussing issues such as disk partitioning, it is important to know a bit about the underlying hardware. Unfortunately, it is easy to become bogged down in details. Therefore, this appendix uses a simplified diagram of a disk drive to help explain what is really happening when a disk drive is partitioned. Figure A.1, “An Unused Disk Drive”, shows a brand-new, unused disk drive.

![Figure A.1. An Unused Disk Drive](image)

Not much to look at, is it? But if we are talking about disk drives on a basic level, it is adequate. Say that we would like to store some data on this drive. As things stand now, it will not work. There is something we need to do first.

A.1.1. It is Not What You Write, it is How You Write It

Experienced computer users probably got this one on the first try. We need to format the drive. Formatting (usually known as “making a file system”) writes information to the drive, creating order out of the empty space in an unformatted drive.

![Figure A.2. Disk Drive with a File System](image)
Appendix A. An Introduction to Disk Partitions

As Figure A.2, "Disk Drive with a File System", implies, the order imposed by a file system involves some trade-offs:

- A small percentage of the drive's available space is used to store file system-related data and can be considered as overhead.

- A file system splits the remaining space into small, consistently-sized segments. For Linux, these segments are known as blocks. ¹

Given that file systems make things like directories and files possible, these trade-offs are usually seen as a small price to pay.

It is also worth noting that there is no single, universal file system. As Figure A.3, "Disk Drive with a Different File System", shows, a disk drive may have one of many different file systems written on it. As you might guess, different file systems tend to be incompatible; that is, an operating system that supports one file system (or a handful of related file system types) may not support another. This last statement is not a hard-and-fast rule, however. For example, Fedora supports a wide variety of file systems (including many commonly used by other operating systems), making data interchange between different file systems easy.

![Figure A.3. Disk Drive with a Different File System](image)

Of course, writing a file system to disk is only the beginning. The goal of this process is to actually store and retrieve data. Let us take a look at our drive after some files have been written to it.

![Figure A.4. Disk Drive with Data Written to It](image)

As Figure A.4, "Disk Drive with Data Written to It", shows, some of the previously-empty blocks are now holding data. However, by just looking at this picture, we cannot determine exactly how many files reside on this drive. There may only be one file or many, as all files use at least one block and some files use multiple blocks. Another important point to note is that the used blocks do not have to form a contiguous region; used and unused blocks may be interspersed. This is known as fragmentation. Fragmentation can play a part when attempting to resize an existing partition.

As with most computer-related technologies, disk drives changed over time after their introduction. In particular, they got bigger. Not larger in physical size, but bigger in their capacity to store information. And, this additional capacity drove a fundamental change in the way disk drives were used.

A.1.2. Partitions: Turning One Drive Into Many

As disk drive capacities soared, some people began to wonder if having all of that formatted space in one big chunk was such a great idea. This line of thinking was driven by several issues, some

---

¹ The term “block” is used in the context of file systems to refer to a contiguous set of bytes that can be independently allocated. In other contexts, such as disk drives, it refers to a small unit of storage that can be independently read or written.
philosophical, some technical. On the philosophical side, above a certain size, it seemed that the additional space provided by a larger drive created more clutter. On the technical side, some file systems were never designed to support anything above a certain capacity. Or the file systems could support larger drives with a greater capacity, but the overhead imposed by the file system to track files became excessive.

The solution to this problem was to divide disks into partitions. Each partition can be accessed as if it was a separate disk. This is done through the addition of a partition table.

### Note

While the diagrams in this chapter show the partition table as being separate from the actual disk drive, this is not entirely accurate. In reality, the partition table is stored at the very start of the disk, before any file system or user data. But for clarity, they are separate in our diagrams.

As Figure A.5, "Disk Drive with Partition Table" shows, the partition table is divided into four sections or four primary partitions. A primary partition is a partition on a hard drive that can contain only one logical drive (or section). Each section can hold the information necessary to define a single partition, meaning that the partition table can define no more than four partitions.

Each partition table entry contains several important characteristics of the partition:

- The points on the disk where the partition starts and ends
- Whether the partition is "active"
- The partition's type

Let us take a closer look at each of these characteristics. The starting and ending points actually define the partition's size and location on the disk. The "active" flag is used by some operating systems' boot loaders. In other words, the operating system in the partition that is marked "active" is booted.

The partition's type can be a bit confusing. The type is a number that identifies the partition's anticipated usage. If that statement sounds a bit vague, that is because the meaning of the partition type is a bit vague. Some operating systems use the partition type to denote a specific file system type, to flag the partition as being associated with a particular operating system, to indicate that the partition contains a bootable operating system, or some combination of the three.

By this point, you might be wondering how all this additional complexity is normally used. Refer to Figure A.6, "Disk Drive With Single Partition", for an example.
Appendix A. An Introduction to Disk Partitions

Figure A.6. Disk Drive With Single Partition

In many cases, there is only a single partition spanning the entire disk, essentially duplicating the method used before partitions. The partition table has only one entry used, and it points to the start of the partition.

We have labeled this partition as being of the "DOS" type. Although it is only one of several possible partition types listed in Table A.1, "Partition Types", it is adequate for the purposes of this discussion.

Table A.1, "Partition Types", contains a listing of some popular (and obscure) partition types, along with their hexadecimal numeric values.

A.1.3. Partitions within Partitions — An Overview of Extended Partitions

Of course, over time it became obvious that four partitions would not be enough. As disk drives continued to grow, it became more and more likely that a person could configure four reasonably-sized partitions and still have disk space left over. There needed to be some way of creating more partitions.

Enter the extended partition. As you may have noticed in Table A.1, “Partition Types”, there is an “Extended” partition type. It is this partition type that is at the heart of extended partitions.

When a partition is created and its type is set to “Extended,” an extended partition table is created. In essence, the extended partition is like a disk drive in its own right — it has a partition table that points to one or more partitions (now called logical partitions, as opposed to the four primary partitions) contained entirely within the extended partition itself. Figure A.7, “Disk Drive With Extended Partition”, shows a disk drive with one primary partition and one extended partition containing two logical partitions (along with some unpartitioned free space).

![Figure A.7. Disk Drive With Extended Partition](image)

As this figure implies, there is a difference between primary and logical partitions — there can only be four primary partitions, but there is no fixed limit to the number of logical partitions that can exist. However, due to the way in which partitions are accessed in Linux, you should avoid defining more than 12 logical partitions on a single disk drive.

Now that we have discussed partitions in general, let us review how to use this knowledge to install Fedora.

A.1.4. Making Room For Fedora

The following list presents some possible scenarios you may face when attempting to repartition your hard disk:

- Unpartitioned free space is available
- An unused partition is available
- Free space in an actively used partition is available

Let us look at each scenario in order.

![Note]

Keep in mind that the following illustrations are simplified in the interest of clarity and do not reflect the exact partition layout that you encounter when actually installing Fedora.
A.1.4.1. Using Unpartitioned Free Space

In this situation, the partitions already defined do not span the entire hard disk, leaving unallocated space that is not part of any defined partition. Figure A.8, "Disk Drive with Unpartitioned Free Space", shows what this might look like.

![Figure A.8. Disk Drive with Unpartitioned Free Space](image)

In Figure A.8, "Disk Drive with Unpartitioned Free Space", 1 represents an undefined partition with unallocated space and 2 represents a defined partition with allocated space.

If you think about it, an unused hard disk also falls into this category. The only difference is that all the space is not part of any defined partition.

In any case, you can create the necessary partitions from the unused space. Unfortunately, this scenario, although very simple, is not very likely (unless you have just purchased a new disk just for Fedora). Most pre-installed operating systems are configured to take up all available space on a disk drive (refer to Section A.1.4.3, "Using Free Space from an Active Partition").

Next, we will discuss a slightly more common situation.

A.1.4.2. Using Space from an Unused Partition

In this case, maybe you have one or more partitions that you do not use any longer. Perhaps you have dabbled with another operating system in the past, and the partition(s) you dedicated to it never seem to be used anymore. Figure A.9, "Disk Drive With an Unused Partition", illustrates such a situation.

![Figure A.9. Disk Drive With an Unused Partition](image)

In Figure A.9, "Disk Drive With an Unused Partition", 1 represents an unused partition and 2 represents reallocating an unused partition for Linux.

If you find yourself in this situation, you can use the space allocated to the unused partition. You first must delete the partition and then create the appropriate Linux partition(s) in its place. You can delete the unused partition and manually create new partitions during the installation process.

A.1.4.3. Using Free Space from an Active Partition

This is the most common situation. It is also, unfortunately, the hardest to handle. The main problem is that, even if you have enough free space, it is presently allocated to a partition that is already in use.
If you purchased a computer with pre-installed software, the hard disk most likely has one massive partition holding the operating system and data.

Aside from adding a new hard drive to your system, you have two choices:

**Destructive Repartitioning**

Basically, you delete the single large partition and create several smaller ones. As you might imagine, any data you had in the original partition is destroyed. This means that making a complete backup is necessary. For your own sake, make two backups, use verification (if available in your backup software), and try to read data from your backup before you delete the partition.

**Warning**

If there was an operating system of some type installed on that partition, it needs to be reinstalled as well. Be aware that some computers sold with pre-installed operating systems may not include the CD-ROM media to reinstall the original operating system. The best time to notice if this applies to your system is before you destroy your original partition and its operating system installation.

After creating a smaller partition for your existing operating system, you can reinstall any software, restore your data, and start your Fedora installation. *Figure A.10, “Disk Drive Being Destructively Repartitioned”* shows this being done.

![Figure A.10. Disk Drive Being Destructively Repartitioned](image)

In *Figure A.10, “Disk Drive Being Destructively Repartitioned”*, 1 represents before and 2 represents after.

**Warning**

As *Figure A.10, “Disk Drive Being Destructively Repartitioned”*, shows, any data present in the original partition is lost without proper backup!

**Non-Destructive Repartitioning**

Here, you run a program that does the seemingly impossible: it makes a big partition smaller without losing any of the files stored in that partition. Many people have found this method to be reliable and trouble-free. What software should you use to perform this feat? There are several disk management software products on the market. Do some research to find the one that is best for your situation.

While the process of non-destructive repartitioning is rather straightforward, there are a number of steps involved:
Appendix A. An Introduction to Disk Partitions

- Compress and backup existing data
- Resize the existing partition
- Create new partition(s)

Next we will look at each step in a bit more detail.

**A.1.4.3.1. Compress existing data**

As Figure A.11, “Disk Drive Being Compressed”, shows, the first step is to compress the data in your existing partition. The reason for doing this is to rearrange the data such that it maximizes the available free space at the “end” of the partition.

![Figure A.11. Disk Drive Being Compressed](image)

In Figure A.11, “Disk Drive Being Compressed”, 1 represents before and 2 represents after.

This step is crucial. Without it, the location of your data could prevent the partition from being resized to the extent desired. Note also that, for one reason or another, some data cannot be moved. If this is the case (and it severely restricts the size of your new partition(s)), you may be forced to destructively repartition your disk.

**A.1.4.3.2. Resize the existing partition**

Figure A.12, “Disk Drive with Partition Resized”, shows the actual resizing process. While the actual result of the resizing operation varies depending on the software used, in most cases the newly freed space is used to create an unformatted partition of the same type as the original partition.

![Figure A.12. Disk Drive with Partition Resized](image)

In Figure A.12, “Disk Drive with Partition Resized”, 1 represents before and 2 represents after.

It is important to understand what the resizing software you use does with the newly freed space, so that you can take the appropriate steps. In the case we have illustrated, it would be best to delete the new DOS partition and create the appropriate Linux partition(s).

**A.1.4.3.3. Create new partition(s)**

As the previous step implied, it may or may not be necessary to create new partitions. However, unless your resizing software is Linux-aware, it is likely that you must delete the partition that was
created during the resizing process. Figure A.13, “Disk Drive with Final Partition Configuration”, shows this being done.

![Figure A.13. Disk Drive with Final Partition Configuration](image)

In Figure A.13, “Disk Drive with Final Partition Configuration”, 1 represents before and 2 represents after.

**Note**

The following information is specific to x86-based computers only.

As a convenience to our customers, we provide the **parted** utility. This is a freely available program that can resize partitions.

If you decide to repartition your hard drive with **parted**, it is important that you be familiar with disk storage and that you perform a backup of your computer data. You should make two copies of all the important data on your computer. These copies should be to removable media (such as tape, CD-ROM, or diskettes), and you should make sure they are readable before proceeding.

Should you decide to use **parted**, be aware that after **parted** runs you are left with two partitions: the one you resized, and the one **parted** created out of the newly freed space. If your goal is to use that space to install Fedora, you should delete the newly created partition, either by using the partitioning utility under your current operating system or while setting up partitions during installation.

### A.1.5. Partition Naming Scheme

Linux refers to disk partitions using a combination of letters and numbers which may be confusing, particularly if you are used to the “C drive” way of referring to hard disks and their partitions. In the DOS/Windows world, partitions are named using the following method:

- Each partition’s type is checked to determine if it can be read by DOS/Windows.
- If the partition’s type is compatible, it is assigned a “drive letter.” The drive letters start with a “C” and move on to the following letters, depending on the number of partitions to be labeled.
- The drive letter can then be used to refer to that partition as well as the file system contained on that partition.

Fedora uses a naming scheme that is more flexible and conveys more information than the approach used by other operating systems. The naming scheme is file-based, with file names in the form of `/dev/xxYN`.

Here is how to decipher the partition naming scheme:

```
/dev/
```

This is the name of the directory in which all device files reside. Since partitions reside on hard disks, and hard disks are devices, the files representing all possible partitions reside in `/dev/`. 
The first two letters of the partition name indicate the type of device on which the partition resides, usually either **hd** (for IDE disks) or **sd** (for SCSI disks).

This letter indicates which device the partition is on. For example, **/dev/hda** (the first IDE hard disk) or **/dev/sdb** (the second SCSI disk).

The final number denotes the partition. The first four (primary or extended) partitions are numbered 1 through 4. Logical partitions start at 5. So, for example, **/dev/hda3** is the third primary or extended partition on the first IDE hard disk, and **/dev/sdb6** is the second logical partition on the second SCSI hard disk.

---

**Note**

There is no part of this naming convention that is based on partition type; unlike DOS/Windows, all partitions can be identified under Fedora. Of course, this does not mean that Fedora can access data on every type of partition, but in many cases it is possible to access data on a partition dedicated to another operating system.

Keep this information in mind; it makes things easier to understand when you are setting up the partitions Fedora requires.

### A.1.6. Disk Partitions and Other Operating Systems

If your Fedora partitions are sharing a hard disk with partitions used by other operating systems, most of the time you will have no problems. However, there are certain combinations of Linux and other operating systems that require extra care.

### A.1.7. Disk Partitions and Mount Points

One area that many people new to Linux find confusing is the matter of how partitions are used and accessed by the Linux operating system. In DOS/Windows, it is relatively simple: Each partition gets a “drive letter.” You then use the correct drive letter to refer to files and directories on its corresponding partition.

This is entirely different from how Linux deals with partitions and, for that matter, with disk storage in general. The main difference is that each partition is used to form part of the storage necessary to support a single set of files and directories. This is done by associating a partition with a directory through a process known as **mounting**. Mounting a partition makes its storage available starting at the specified directory (known as a **mount point**).

For example, if partition **/dev/hda5** is mounted on **/usr/**, that would mean that all files and directories under **/usr/** physically reside on **/dev/hda5**. So the file **/usr/share/doc/FAQ/txt/Linux-FAQ** would be stored on **/dev/hda5**, while the file **/etc/gdm/custom.conf** would not.

Continuing our example, it is also possible that one or more directories below **/usr/** would be mount points for other partitions. For instance, a partition (say, **/dev/hda7**) could be mounted on **/usr/** **local/**, meaning that **/usr/local/man/whatis** would then reside on **/dev/hda7** rather than **/dev/hda5**.
A.1.8. How Many Partitions?

At this point in the process of preparing to install Fedora, you must give some consideration to the number and size of the partitions to be used by your new operating system. The question of "how many partitions" continues to spark debate within the Linux community and, without any end to the debate in sight, it is safe to say that there are probably as many partition layouts as there are people debating the issue.

Keeping this in mind, we recommend that, unless you have a reason for doing otherwise, you should at least create the following partitions: swap, /boot/, and / (root).

For more information, refer to Section 8.17.5, "Recommended Partitioning Scheme".
Appendix B. ISCSI disks

Internet Small Computer System Interface (iSCSI) is a protocol that allows computers to communicate with storage devices by SCSI requests and responses carried over TCP/IP. Because iSCSI is based on the standard SCSI protocols, it uses some terminology from SCSI. The device on the SCSI bus to which requests get sent (and which answers these requests) is known as the target and the device issuing requests is known as the initiator. In other words, an iSCSI disk is a target and the iSCSI software equivalent of a SCSI controller or SCSI Host Bus Adapter (HBA) is called an initiator. This appendix only covers Linux as an iSCSI initiator: how Linux uses iSCSI disks, but not how Linux hosts iSCSI disks.

Linux has a software iSCSI initiator in the kernel that takes the place and form of a SCSI HBA driver and therefore allows Linux to use iSCSI disks. However, as iSCSI is a fully network-based protocol, iSCSI initiator support needs more than just the ability to send SCSI packets over the network. Before Linux can use an iSCSI target, Linux must find the target on the network and make a connection to it. In some cases, Linux must send authentication information to gain access to the target. Linux must also detect any failure of the network connection and must establish a new connection, including logging in again if necessary.

The discovery, connection, and logging in is handled in userspace by the `iscsiadm` utility, and the error handling is also handled in userspace by `iscsid`.

Both `iscsiadm` and `iscsid` are part of the `iscsi-initiator-utils` package under Fedora.

B.1. iSCSI disks in anaconda

Anaconda can discover (and then log in to) iSCSI disks in two ways:

1. When anaconda starts, it checks if the BIOS or add-on boot ROMs of the system support iSCSI Boot Firmware Table (iBFT), a BIOS extension for systems which can boot from iSCSI. If the BIOS supports iBFT, anaconda will read the iSCSI target information for the configured boot disk from the BIOS and log in to this target, making it available as an installation target.

2. If you select the Specialized Storage Devices option during installation, the storage device selection screen presents you with an Add Advanced Target button. If you click this button, you can add iSCSI target information like the discovery IP address. Anaconda probes the given IP address and logs in to any targets that it finds. See Section 8.8.1.1, “Advanced Storage Options” for the details that you can specify for iSCSI targets.

While anaconda uses iscsiadm to find and log into iSCSI targets, iscsiadm automatically stores any information about these targets in the iscsiadm iSCSI database. Anaconda then copies this database to the installed system and marks any iSCSI targets not used for / so that the system will automatically log in to them when it starts. If / is placed on an iSCSI target, initrd will log into this target and anaconda does not include this target in start up scripts to avoid multiple attempts to log into the same target.

If / is placed on an iSCSI target, anaconda sets NetworkManager to ignore any network interfaces that were active during the installation process. These interfaces will also be configured by initrd when the system starts. If NetworkManager were to reconfigure these interfaces, the system would lose its connection to /.

B.2. iSCSI disks during start up

iSCSI-related events might occur at a number of points while the system starts:
Appendix B. iSCSI disks

1. The init script in the initrd will log in to iSCSI targets used for / (if any). This is done using the iscsistart utility (which can do this without requiring iscsid to run).

2. When the root filesystem has been mounted and the various service initscripts get run, the iscsid initscript will get called. This script will then start iscsid if any iSCSI targets are used for /, or if any targets in the iSCSI database are marked to be logged in to automatically.

3. After the classic network service script has been run (or would have been run if enabled) the iscsi initscript will run. If the network is accessible, this will log in to any targets in the iSCSI database which are marked to be logged in to automatically. If the network is not accessible, this script will exit quietly.

4. When using NetworkManager to access the network (instead of the classic network service script), NetworkManager will call the iscsi initscript. See: /etc/NetworkManager/dispatcher.d/04-iscsi

**Important**

Because NetworkManager is installed in /usr, you cannot use it to configure network access if /usr is on network-attached storage such as an iSCSI target.

If iscsid is not needed as the system starts, it will not start automatically. If you start iscsiadm, iscsiadm will start iscsid in turn.
Appendix C. Disk Encryption

C.1. What is block device encryption?
Block device encryption protects the data on a block device by encrypting it. To access the device's decrypted contents, a user must provide a passphrase or key as authentication. This provides additional security beyond existing OS security mechanisms in that it protects the device's contents even if it has been physically removed from the system.

C.2. Encrypting block devices using dm-crypt/LUKS

Linux Unified Key Setup (LUKS) is a specification for block device encryption. It establishes an on-disk format for the data, as well as a passphrase/key management policy.

LUKS uses the kernel device mapper subsystem via the dm-crypt module. This arrangement provides a low-level mapping that handles encryption and decryption of the device's data. User-level operations, such as creating and accessing encrypted devices, are accomplished through the use of the cryptsetup utility.

C.2.1. Overview of LUKS

• What LUKS does:
  • LUKS encrypts entire block devices
  • LUKS is thereby well-suited for protecting the contents of mobile devices such as:
    • Removable storage media
    • Laptop disk drives
  • The underlying contents of the encrypted block device are arbitrary.
    • This makes it useful for encrypting swap devices.
    • This can also be useful with certain databases that use specially formatted block devices for data storage.
  • LUKS uses the existing device mapper kernel subsystem.
    • This is the same subsystem used by LVM, so it is well tested.
  • LUKS provides passphrase strengthening.
    • This protects against dictionary attacks.
  • LUKS devices contain multiple key slots.
    • This allows users to add backup keys/passphrases.

• What LUKS does not do:
  • LUKS is not well-suited for applications requiring many (more than eight) users to have distinct access keys to the same device.
  • LUKS is not well-suited for applications requiring file-level encryption.

More detailed information about LUKS is available from the project website at http://code.google.com/p/cryptsetup/.
C.2.2. How will I access the encrypted devices after installation? (System Startup)
During system startup you will be presented with a passphrase prompt. After the correct passphrase has been provided the system will continue to boot normally. If you used different passphrases for multiple encrypted devices you may need to enter more than one passphrase during the startup.

Tip
Consider using the same passphrase for all encrypted block devices in a given system. This will simplify system startup and you will have fewer passphrases to remember. Just make sure you choose a good passphrase!

C.2.3. Choosing a Good Passphrase
While dm-crypt/LUKS supports both keys and passphrases, the anaconda installer only supports the use of passphrases for creating and accessing encrypted block devices during installation.

LUKS does provide passphrase strengthening but it is still a good idea to choose a good (meaning "difficult to guess") passphrase. Note the use of the term "passphrase", as opposed to the term "password". This is intentional. Providing a phrase containing multiple words to increase the security of your data is important.

C.3. Creating Encrypted Block Devices in Anaconda
You can create encrypted devices during system installation. This allows you to easily configure a system with encrypted partitions.

To enable block device encryption, check the "Encrypt System" checkbox when selecting automatic partitioning or the "Encrypt" checkbox when creating an individual partition, software RAID array, or logical volume. After you finish partitioning, you will be prompted for an encryption passphrase. This passphrase will be required to access the encrypted devices. If you have pre-existing LUKS devices and provided correct passphrases for them earlier in the install process the passphrase entry dialog will also contain a checkbox. Checking this checkbox indicates that you would like the new passphrase to be added to an available slot in each of the pre-existing encrypted block devices.

Tip
Checking the "Encrypt System" checkbox on the "Automatic Partitioning" screen and then choosing "Create custom layout" does not cause any block devices to be encrypted automatically.

Tip
You can use kickstart to set a separate passphrase for each new encrypted block device.

C.3.1. What Kinds of Block Devices Can Be Encrypted?
Most types of block devices can be encrypted using LUKS. From anaconda you can encrypt partitions, physical volumes, LVM logical volumes, and software RAID arrays.
C.3.2. Saving Passphrases

If you use a kickstart file during installation, you can automatically save the passphrases used during installation to an encrypted file on the local file system. To use this feature, you must have an X.509 certificate available at a location that `anaconda` can access. To specify the URL of this certificate, add the `--escrowcert` parameter to any of the `autopart, logvol, part` or `raid` commands. During installation, the encryption keys for the specified devices are saved in files in `/ (root), encrypted with the certificate.

Note that this feature is available only while performing a kickstart installation. Refer to Chapter 14, Kickstart Installations for more detail.

C.3.3. Creating and Saving Backup Passphrases

If you use a kickstart file during installation, `anaconda` can add a randomly generated backup passphrase to each block device on the system and save each passphrase to an encrypted file on the local file system. Specify the URL of this certificate with the `--escrowcert` parameter as described in Section C.3.2, “Saving Passphrases”, followed by the `--backuppassphrase` parameter for each of the kickstart commands that relate to the devices for which you want to create backup passphrases.

Note that this feature is available only while performing a kickstart installation. Refer to Chapter 14, Kickstart Installations for more detail.

C.4. Creating Encrypted Block Devices on the Installed System After Installation

Encrypted block devices can be created and configured after installation.

C.4.1. Create the block devices

Create the block devices you want to encrypt by using `parted, pvcreate, lvcreate` and `mdadm`.

C.4.2. Optional: Fill the device with random data

Filling `<device>` (eg: `/dev/sda3`) with random data before encrypting it greatly increases the strength of the encryption. The downside is that it can take a very long time.

⚠️ Warning

The commands below will destroy any existing data on the device.

- The best way, which provides high quality random data but takes a long time (several minutes per gigabyte on most systems):

  ```bash
  dd if=/dev/urandom of=<device>
  ```

- Fastest way, which provides lower quality random data:

  ```bash
  badblocks -c 10240 -s -w -t random -v <device>
  ```
C.4.3. Format the device as a dm-crypt/LUKS encrypted device

**Warning**

The command below will destroy any existing data on the device.

```
cryptsetup luksFormat <device>
```

**Tip**

For more information, read the `cryptsetup(8)` man page.

After supplying the passphrase twice the device will be formatted for use. To verify, use the following command:

```
cryptsetup isLuks <device> && echo Success
```

To see a summary of the encryption information for the device, use the following command:

```
cryptsetup luksDump <device>
```

C.4.4. Create a mapping to allow access to the device's decrypted contents

To access the device's decrypted contents, a mapping must be established using the kernel `device-mapper`.

It is useful to choose a meaningful name for this mapping. LUKS provides a UUID (Universally Unique Identifier) for each device. This, unlike the device name (eg: `/dev/sda3`), is guaranteed to remain constant as long as the LUKS header remains intact. To find a LUKS device's UUID, run the following command:

```
cryptsetup luksUUID <device>
```

An example of a reliable, informative and unique mapping name would be `luks-<uuid>`, where `<uuid>` is replaced with the device's LUKS UUID (eg: `luks-50ec957a-5b5a-47ee-85e6-f8085bbc97a8`). This naming convention might seem unwieldy but is it not necessary to type it often.

```
cryptsetup luksOpen <device> <name>
```

There should now be a device node, `/dev/mapper/<name>`, which represents the decrypted device. This block device can be read from and written to like any other unencrypted block device.

To see some information about the mapped device, use the following command:

```
dmsetup info <name>
```
C.4.5. Create filesystems on the mapped device, or continue to build complex storage structures using the mapped device

Use the mapped device node (/dev/mapper/<name>) as any other block device. To create an ext2 filesystem on the mapped device, use the following command:

mke2fs /dev/mapper/<name>

To mount this filesystem on /mnt/test, use the following command:

mount /dev/mapper/<name> /mnt/test

C.4.6. Add the mapping information to /etc/crypttab

In order for the system to set up a mapping for the device, an entry must be present in the /etc/crypttab file. If the file doesn't exist, create it and change the owner and group to root (root:root) and change the mode to 0744. Add a line to the file with the following format:

```
<name>  <device>  none
```

The <device> field should be given in the form "UUID=<luks_uuid>" where <luks_uuid> is the LUKS UUID as given by the command cryptsetup luksUUID <device>. This ensures the correct device will be identified and used even if the device node (eg: /dev/sda5) changes.

Tip

For details on the format of the /etc/crypttab file, read the crypttab(5) man page.

C.4.7. Add an entry to /etc/fstab

Add an entry to /etc/fstab. This is only necessary if you want to establish a persistent association between the device and a mountpoint. Use the decrypted device, /dev/mapper/<name> in the /etc/fstab file.

In many cases it is desirable to list devices in /etc/fstab by UUID or by a filesystem label. The main purpose of this is to provide a constant identifier in the event that the device name (eg: /dev/sda4) changes. LUKS device names in the form of /dev/mapper/luks-<luks_uuid> are based only on the device's LUKS UUID, and are therefore guaranteed to remain constant. This fact makes them suitable for use in /etc/fstab.
C.5. Common Post-Installation Tasks
The following sections are about common post-installation tasks.

C.5.1. Set a randomly generated key as an additional way to access an encrypted block device
These sections are about generating keys and adding keys.

C.5.1.1. Generate a key
This will generate a 256-bit key in the file $HOME/keyfile.

```
dd if=/dev/urandom of=$HOME/keyfile bs=32 count=1
chmod 600 $HOME/keyfile
```

C.5.1.2. Add the key to an available keyslot on the encrypted device

```
cryptsetup luksAddKey <device> ~/keyfile
```

C.5.2. Add a new passphrase to an existing device

```
cryptsetup luksAddKey <device>
```
After being prompted for any one of the existing passprases for authentication, you will be prompted to enter the new passphrase.

C.5.3. Remove a passphrase or key from a device

```
cryptsetup luksRemoveKey <device>
```
You will be prompted for the passphrase you wish to remove and then for any one of the remaining passphrases for authentication.
Appendix D. Understanding LVM

LVM (Logical Volume Management) partitions provide a number of advantages over standard partitions. LVM partitions are formatted as physical volumes. One or more physical volumes are combined to form a volume group. Each volume group’s total storage is then divided into one or more logical volumes. The logical volumes function much like standard partitions. They have a file system type, such as ext4, and a mount point.

The /boot Partition and LVM

On most architectures, the boot loader cannot read LVM volumes. You must make a standard, non-LVM disk partition for your /boot partition.

However, on System z, the zipl boot loader supports /boot on LVM logical volumes with linear mapping.

To understand LVM better, imagine the physical volume as a pile of blocks. A block is simply a storage unit used to store data. Several piles of blocks can be combined to make a much larger pile, just as physical volumes are combined to make a volume group. The resulting pile can be subdivided into several smaller piles of arbitrary size, just as a volume group is allocated to several logical volumes.

An administrator may grow or shrink logical volumes without destroying data, unlike standard disk partitions. If the physical volumes in a volume group are on separate drives or RAID arrays then administrators may also spread a logical volume across the storage devices.

You may lose data if you shrink a logical volume to a smaller capacity than the data on the volume requires. To ensure maximum flexibility, create logical volumes to meet your current needs, and leave excess storage capacity unallocated. You may safely grow logical volumes to use unallocated space, as your needs dictate.

LVM and the Default Partition Layout

By default, the installation process creates / and swap partitions within LVM volumes, with a separate /boot partition.
Appendix E. The GRUB Boot Loader

When a computer running Linux is turned on, the operating system is loaded into memory by a special program called a boot loader. A boot loader usually exists on the system's primary hard drive (or other media device) and has the sole responsibility of loading the Linux kernel with its required files or (in some cases) other operating systems into memory.

E.1. Boot Loaders and System Architecture

This appendix discusses commands and configuration options for the GRUB boot loader included with Fedora for the x86 architecture.

Important — Supported file systems

The GRUB bootloader in Fedora 14 supports only the ext2, ext3, and ext4 (recommended) file systems. You cannot use any other file system for /boot, such as Btrfs, XFS, or VFAT.

E.2. GRUB

The GNU GRand Unified Boot loader (GRUB) is a program which enables the selection of the installed operating system or kernel to be loaded at system boot time. It also allows the user to pass arguments to the kernel.

E.2.1. GRUB and the x86 Boot Process

This section discusses the specific role GRUB plays when booting an x86 system. For a look at the overall boot process, refer to Section F.2, “A Detailed Look at the Boot Process”.

GRUB loads itself into memory in the following stages:

1. The Stage 1 or primary boot loader is read into memory by the BIOS from the MBR. The primary boot loader exists on less than 512 bytes of disk space within the MBR and is capable of loading either the Stage 1.5 or Stage 2 boot loader.

2. The Stage 1.5 boot loader is read into memory by the Stage 1 boot loader, if necessary. Some hardware requires an intermediate step to get to the Stage 2 boot loader. This is sometimes true when the /boot partition is above the 1024 cylinder head of the hard drive or when using LBA mode. The Stage 1.5 boot loader is found either on the /boot partition or on a small part of the MBR and the /boot partition.

3. The Stage 2 or secondary boot loader is read into memory. The secondary boot loader displays the GRUB menu and command environment. This interface allows the user to select which kernel or operating system to boot, pass arguments to the kernel, or look at system parameters.

4. The secondary boot loader reads the operating system or kernel as well as the contents of /boot/sysroot into memory. Once GRUB determines which operating system or kernel to start, it loads it into memory and transfers control of the machine to that operating system.

The method used to boot Linux is called direct loading because the boot loader loads the operating system directly. There is no intermediary between the boot loader and the kernel.

The boot process used by other operating systems may differ. For example, the Microsoft® Windows® operating system, as well as other operating systems, are loaded using chain loading. Under this
method, the MBR points to the first sector of the partition holding the operating system, where it finds the files necessary to actually boot that operating system.

GRUB supports both direct and chain loading boot methods, allowing it to boot almost any operating system.

**Warning**

During installation, Microsoft's DOS and Windows installation programs completely overwrite the MBR, destroying any existing boot loaders. If creating a dual-boot system, it is best to install the Microsoft operating system first.

### E.2.2. Features of GRUB

GRUB contains several features that make it preferable to other boot loaders available for the x86 architecture. Below is a partial list of some of the more important features:

- **GRUB provides a true command-based, pre-OS environment on x86 machines.** This feature affords the user maximum flexibility in loading operating systems with specified options or gathering information about the system. For years, many non-x86 architectures have employed pre-OS environments that allow system booting from a command line.

- **GRUB supports Logical Block Addressing (LBA) mode.** LBA places the addressing conversion used to find files in the hard drive's firmware, and is used on many IDE and all SCSI hard devices. Before LBA, boot loaders could encounter the 1024-cylinder BIOS limitation, where the BIOS could not find a file after the 1024 cylinder head of the disk. LBA support allows GRUB to boot operating systems from partitions beyond the 1024-cylinder limit, so long as the system BIOS supports LBA mode. Most modern BIOS revisions support LBA mode.

- **GRUB can read ext2 partitions.** This functionality allows GRUB to access its configuration file, `/boot/grub/grub.conf`, every time the system boots, eliminating the need for the user to write a new version of the first stage boot loader to the MBR when configuration changes are made. The only time a user needs to reinstall GRUB on the MBR is if the physical location of the `/boot/` partition is moved on the disk. For details on installing GRUB to the MBR, refer to Section E.3, "Installing GRUB".

### E.3. Installing GRUB

If GRUB was not installed during the installation process, it can be installed afterward. Once installed, it automatically becomes the default boot loader.

Before installing GRUB, make sure to use the latest GRUB package available or use the GRUB package from the installation DVD. For instructions on installing packages, refer to the chapter titled Package Management with RPM in the Fedora Deployment Guide.

Once the GRUB package is installed, open a root shell prompt and run the command `/sbin/grub-install <location>`, where `<location>` is the location that the GRUB Stage 1 boot loader should be installed. For example, the following command installs GRUB to the MBR of the master IDE device on the primary IDE bus:

```
/sbin/grub-install /dev/hda
```

The next time the system boots, the GRUB graphical boot loader menu appears before the kernel loads into memory.
GRUB cannot construct a software RAID. Therefore, the /boot directory must reside on a single, specific disk partition. The /boot directory cannot be striped across multiple disks, as in a level 0 RAID. To use a level 0 RAID on your system, place /boot on a separate partition outside the RAID.

Similarly, because the /boot directory must reside on a single, specific disk partition, GRUB cannot boot the system if the disk holding that partition fails or is removed from the system. This is true even if the disk is mirrored in a level 1 RAID.

Note that these issues apply only to RAID that is implemented in software, where the individual disks that make up the array are still visible as individual disks on the system. These issues do not apply to hardware RAID where multiple disks are represented as a single device.

E.4. GRUB Terminology

One of the most important things to understand before using GRUB is how the program refers to devices, such as hard drives and partitions. This information is particularly important when configuring GRUB to boot multiple operating systems.

E.4.1. Device Names

When referring to a specific device with GRUB, do so using the following format (note that the parentheses and comma are very important syntactically):

\[(<\text{type-of-device}><\text{bios-device-number}>,<\text{partition-number}>\)]

The \(<\text{type-of-device}>\) specifies the type of device from which GRUB boots. The two most common options are \(\text{hd}\) for a hard disk or \(\text{fd}\) for a 3.5 diskette. A lesser used device type is also available called \(\text{nd}\) for a network disk. Instructions on configuring GRUB to boot over the network are available online at http://www.gnu.org/software/grub/manual/.

The \(<\text{bios-device-number}>\) is the BIOS device number. The primary IDE hard drive is numbered \(0\) and a secondary IDE hard drive is numbered \(1\). This syntax is roughly equivalent to that used for devices by the kernel. For example, the \(\text{a}\) in \(\text{hda}\) for the kernel is analogous to the \(0\) in \(\text{hd0}\) for GRUB, the \(\text{b}\) in \(\text{hdb}\) is analogous to the \(1\) in \(\text{hd1}\), and so on.

The \(<\text{partition-number}>\) specifies the number of a partition on a device. Like the \(<\text{bios-device-number}>\), most types of partitions are numbered starting at \(0\). However, BSD partitions are specified using letters, with \(\text{a}\) corresponding to \(0\), \(\text{b}\) corresponding to \(1\), and so on.

Note

The numbering system for devices under GRUB always begins with \(0\), not \(1\). Failing to make this distinction is one of the most common mistakes made by new users.

To give an example, if a system has more than one hard drive, GRUB refers to the first hard drive as \((\text{hd0})\) and the second as \((\text{hd1})\). Likewise, GRUB refers to the first partition on the first drive as \((\text{hd0,0})\) and the third partition on the second hard drive as \((\text{hd1,2})\).

In general the following rules apply when naming devices and partitions under GRUB:
Appendix E. The GRUB Boot Loader

- It does not matter if system hard drives are IDE or SCSI, all hard drives begin with the letters `hd`. The letters `fd` are used to specify 3.5 diskettes.

- To specify an entire device without respect to partitions, leave off the comma and the partition number. This is important when telling GRUB to configure the MBR for a particular disk. For example, `(hd0)` specifies the MBR on the first device and `(hd3)` specifies the MBR on the fourth device.

- If a system has multiple drive devices, it is very important to know how the drive boot order is set in the BIOS. This is a simple task if a system has only IDE or SCSI drives, but if there is a mix of devices, it becomes critical that the type of drive with the boot partition be accessed first.

E.4.2. File Names and Blocklists

When typing commands to GRUB that reference a file, such as a menu list, it is necessary to specify an absolute file path immediately after the device and partition numbers.

The following illustrates the structure of such a command:

```
(<device-type><device-number>,<partition-number>)</path/to/file>
```

In this example, replace `<device-type>` with `hd`, `fd`, or `nd`. Replace `<device-number>` with the integer for the device. Replace `</path/to/file>` with an absolute path relative to the top-level of the device.

It is also possible to specify files to GRUB that do not actually appear in the file system, such as a chain loader that appears in the first few blocks of a partition. To load such files, provide a `blocklist` that specifies block by block where the file is located in the partition. Since a file is often comprised of several different sets of blocks, blocklists use a special syntax. Each block containing the file is specified by an offset number of blocks, followed by the number of blocks from that offset point. Block offsets are listed sequentially in a comma-delimited list.

The following is a sample blocklist:

```
0+50,100+25,200+1
```

This sample blocklist specifies a file that starts at the first block on the partition and uses blocks 0 through 49, 100 through 124, and 200.

Knowing how to write blocklists is useful when using GRUB to load operating systems which require chain loading. It is possible to leave off the offset number of blocks if starting at block 0. As an example, the chain loading file in the first partition of the first hard drive would have the following name:

```
(hd0,0)+1
```

The following shows the `chainloader` command with a similar blocklist designation at the GRUB command line after setting the correct device and partition as root:

```
chainloader +1
```
E.4.3. The Root File System and GRUB

The use of the term root file system has a different meaning in regard to GRUB. It is important to remember that GRUB's root file system has nothing to do with the Linux root file system.

The GRUB root file system is the top level of the specified device. For example, the image file (hd0, 0)/grub/splash.xpm.gz is located within the /grub/ directory at the top-level (or root) of the (hd0, 0) partition (which is actually the /boot/ partition for the system).

Next, the kernel command is executed with the location of the kernel file as an option. Once the Linux kernel boots, it sets up the root file system that Linux users are familiar with. The original GRUB root file system and its mounts are forgotten; they only existed to boot the kernel file.

Refer to the root and kernel commands in Section E.6, “GRUB Commands” for more information.

E.5. GRUB Interfaces

GRUB features three interfaces which provide different levels of functionality. Each of these interfaces allows users to boot the Linux kernel or another operating system.

The interfaces are as follows:

- **Note**

  The following GRUB interfaces can only be accessed by pressing any key within the three seconds of the GRUB menu bypass screen.

Menu Interface

This is the default interface shown when GRUB is configured by the installation program. A menu of operating systems or preconfigured kernels are displayed as a list, ordered by name. Use the arrow keys to select an operating system or kernel version and press the Enter key to boot it. If you do nothing on this screen, then after the time out period expires GRUB will load the default option.

Press the e key to enter the entry editor interface or the c key to load a command line interface.

Refer to Section E.7, “GRUB Menu Configuration File” for more information on configuring this interface.

Menu Entry Editor Interface

To access the menu entry editor, press the e key from the boot loader menu. The GRUB commands for that entry are displayed here, and users may alter these command lines before booting the operating system by adding a command line (o inserts a new line after the current line and o inserts a new line before it), editing one (e), or deleting one (d).

After all changes are made, the b key executes the commands and boots the operating system. The Esc key discards any changes and reloads the standard menu interface. The c key loads the command line interface.

- **Note**

  For information about changing runlevels using the GRUB menu entry editor, refer to Section E.8, “Changing Runlevels at Boot Time”.

The Root File System and GRUB

261
Command Line Interface

The command line interface is the most basic GRUB interface, but it is also the one that grants the most control. The command line makes it possible to type any relevant GRUB commands followed by the Enter key to execute them. This interface features some advanced shell-like features, including Tab key completion based on context, and Ctrl key combinations when typing commands, such as Ctrl+a to move to the beginning of a line and Ctrl+e to move to the end of a line. In addition, the arrow, Home, End, and Delete keys work as they do in the bash shell.

Refer to Section E.6, "GRUB Commands" for a list of common commands.

E.5.1. Interfaces Load Order

When GRUB loads its second stage boot loader, it first searches for its configuration file. Once found, the menu interface bypass screen is displayed. If a key is pressed within three seconds, GRUB builds a menu list and displays the menu interface. If no key is pressed, the default kernel entry in the GRUB menu is used.

If the configuration file cannot be found, or if the configuration file is unreadable, GRUB loads the command line interface, allowing the user to type commands to complete the boot process.

If the configuration file is not valid, GRUB prints out the error and asks for input. This helps the user see precisely where the problem occurred. Pressing any key reloads the menu interface, where it is then possible to edit the menu option and correct the problem based on the error reported by GRUB. If the correction fails, GRUB reports an error and reloads the menu interface.

E.6. GRUB Commands

GRUB allows a number of useful commands in its command line interface. Some of the commands accept options after their name; these options should be separated from the command and other options on that line by space characters.

The following is a list of useful commands:

- **boot** — Boots the operating system or chain loader that was last loaded.

- **chainloader <path/to/file>** — Loads the specified file as a chain loader. If the file is located on the first sector of the specified partition, use the blocklist notation, +1, instead of the file name.

  The following is an example chainloader command:

  ```
  chainloader +1
  ```

- **displaymem** — Displays the current use of memory, based on information from the BIOS. This is useful to determine how much RAM a system has prior to booting it.

- **initrd <path/to/initrd>** — Enables users to specify an initial RAM disk to use when booting. An initrd is necessary when the kernel needs certain modules in order to boot properly, such as when the root partition is formatted with the ext3 or ext4 file system.

  The following is an example initrd command:

  ```
  initrd /initrd-2.6.8-1.523.img
  ```
• **install** <stage-1> <install-disk> <stage-2> p config-file — Installs GRUB to the system MBR.

• **<stage-1>** — Signifies a device, partition, and file where the first boot loader image can be found, such as (hd0,0)/grub/stage1.

• **<install-disk>** — Specifies the disk where the stage 1 boot loader should be installed, such as (hd0).

• **<stage-2>** — Passes the stage 2 boot loader location to the stage 1 boot loader, such as (hd0,0)/grub/stage2.

• **p config-file** — This option tells the install command to look for the menu configuration file specified by <config-file>, such as (hd0,0)/grub/grub.conf.

**Warning**

The install command overwrites any information already located on the MBR.

• **kernel** </path/to/kernel> <option-1> <option-N> ... — Specifies the kernel file to load when booting the operating system. Replace </path/to/kernel> with an absolute path from the partition specified by the root command. Replace <option-1> with options for the Linux kernel, such as root=/dev/VolGroup00/LogVol00 to specify the device on which the root partition for the system is located. Multiple options can be passed to the kernel in a space separated list.

The following is an example kernel command:

```
kernel /vmlinuz-2.6.8-1.523 ro root=/dev/VolGroup00/LogVol00
```

The option in the previous example specifies that the root file system for Linux is located on the hda5 partition.

• **root** (<device-type><device-number>,<partition>) — Configures the root partition for GRUB, such as (hd0,0), and mounts the partition.

The following is an example root command:

```
root (hd0,0)
```

• **rootnoverify** (<device-type><device-number>,<partition>) — Configures the root partition for GRUB, just like the root command, but does not mount the partition.

Other commands are also available; type help --all for a full list of commands. For a description of all GRUB commands, refer to the documentation available online at [http://www.gnu.org/software/grub/manual/](http://www.gnu.org/software/grub/manual/).

### E.7. GRUB Menu Configuration File

The configuration file (/boot/grub/grub.conf), which is used to create the list of operating systems to boot in GRUB’s menu interface, essentially allows the user to select a pre-set group of
Appendix E. The GRUB Boot Loader

commands to execute. The commands given in Section E.6, “GRUB Commands” can be used, as well as some special commands that are only available in the configuration file.

E.7.1. Configuration File Structure

The GRUB menu interface configuration file is /boot/grub/grub.conf. The commands to set the global preferences for the menu interface are placed at the top of the file, followed by stanzas for each operating kernel or operating system listed in the menu.

The following is a very basic GRUB menu configuration file designed to boot either Fedora or Microsoft Windows Vista:

```
default=0
timeout=10
splashimage=(hd0,0)/grub/splash.xpm.gz
hiddenmenu
title Fedora (2.6.27.19-170.2.35.fc10.i686)
root (hd0,1)
kernel /vmlinuz-2.6.27.19-170.2.35.fc10.i686 ro root=UUID=04a07c13-e6bf-6d5a-b207-002689545705 rhgb quiet
initrd /initrd-2.6.27.19-170.2.35.fc10.i686.img
# section to load Windows
title Windows
rootnoverify (hd0,0)
chainloader +1
```

This file configures GRUB to build a menu with Fedora as the default operating system and sets it to autoboot after 10 seconds. Two sections are given, one for each operating system entry, with commands specific to the system disk partition table.

**Note**

Note that the default is specified as an integer. This refers to the first title line in the GRUB configuration file. For the Windows section to be set as the default in the previous example, change the default=0 to default=1.

Configuring a GRUB menu configuration file to boot multiple operating systems is beyond the scope of this chapter. Consult Section E.9, “Additional Resources” for a list of additional resources.

E.7.2. Configuration File Directives

The following are directives commonly used in the GRUB menu configuration file:

- **chainloader <path/to/file>** — Loads the specified file as a chain loader. Replace `<path/to/file>` with the absolute path to the chain loader. If the file is located on the first sector of the specified partition, use the blocklist notation, `+1`.

- **color <normal-color> <selected-color>** — Allows specific colors to be used in the menu, where two colors are configured as the foreground and background. Use simple color names such as red/black. For example:

  ```
  color red/black green/blue
  ```
• **default=<integer>** — Replace `<integer>` with the default entry title number to be loaded if the menu interface times out.

• **fallback=<integer>** — Replace `<integer>` with the entry title number to try if the first attempt fails.

• **hiddenmenu** — Prevents the GRUB menu interface from being displayed, loading the **default** entry when the **timeout** period expires. The user can see the standard GRUB menu by pressing the **Esc** key.

• **initrd </path/to/initrd>** — Enables users to specify an initial RAM disk to use when booting. Replace </path/to/initrd> with the absolute path to the initial RAM disk.

• **kernel </path/to/kernel> <option-1> <option-N>** — Specifies the kernel file to load when booting the operating system. Replace </path/to/kernel> with an absolute path from the partition specified by the root directive. Multiple options can be passed to the kernel when it is loaded.

  These options include:
  • **rhgb** *(Red Hat graphical boot)* — displays an animation during the boot process, rather than lines of text.
  • **quiet** — suppresses all but the most important messages in the part of the boot sequence before the Red Hat graphical boot animation begins.

• **password=<password>** — Prevents a user who does not know the password from editing the entries for this menu option.

  Optionally, it is possible to specify an alternate menu configuration file after the **password=<password>** directive. In this case, GRUB restarts the second stage boot loader and uses the specified alternate configuration file to build the menu. If an alternate menu configuration file is left out of the command, a user who knows the password is allowed to edit the current configuration file.

  For more information about securing GRUB, refer to the chapter titled **Workstation Security** in the **Fedora Linux Deployment Guide**.

• **map** — Swaps the numbers assigned to two hard drives. For example:

```plaintext
map (hd0) (hd3)
map (hd3) (hd0)
```

assigns the number 0 to the fourth hard drive, and the number 3 to the first hard drive. This option is especially useful if you configure your system with an option to boot a Windows operating system, because the Windows boot loader must find the Windows installation on the first hard drive.

For example, if your Windows installation is on the fourth hard drive, the following entry in **grub.conf** will allow the Windows boot loader to load Windows correctly:

```plaintext
title Windows
map (hd0) (hd3)
map (hd3) (hd0)
rootnoverify (hd3,0)
chainloader +1
```
Appendix E. The GRUB Boot Loader

- **root** (<device-type><device-number>,<partition>) — Configures the root partition for GRUB, such as (hd0,0), and mounts the partition.

- **rootnoverify** (<device-type><device-number>,<partition>) — Configures the root partition for GRUB, just like the root command, but does not mount the partition.

- **timeout=<integer>** — Specifies the interval, in seconds, that GRUB waits before loading the entry designated in the default command.

- **splashimage=<path-to-image>** — Specifies the location of the splash screen image to be used when GRUB boots.

- **title group-title** — Specifies a title to be used with a particular group of commands used to load a kernel or operating system.

To add human-readable comments to the menu configuration file, begin the line with the hash mark character (#).

### E.8. Changing Runlevels at Boot Time

Under Fedora, it is possible to change the default runlevel at boot time.

To change the runlevel of a single boot session, use the following instructions:

- When the GRUB menu bypass screen appears at boot time, press any key to enter the GRUB menu (within the first three seconds).

- Press the a key to append to the kernel command.

- Add <space><runlevel> at the end of the boot options line to boot to the desired runlevel. For example, the following entry would initiate a boot process into runlevel 3:

  ```
  grub append> ro root=/dev/VolGroup00/LogVol00 rhgb quiet 3
  ```

### E.9. Additional Resources

This chapter is only intended as an introduction to GRUB. Consult the following resources to discover more about how GRUB works.

#### E.9.1. Installed Documentation

- `/usr/share/doc/grub-<version-number>/` — This directory contains good information about using and configuring GRUB, where `<version-number>` corresponds to the version of the GRUB package installed.

- `info grub` — The GRUB info page contains a tutorial, a user reference manual, a programmer reference manual, and a FAQ document about GRUB and its usage.

#### E.9.2. Useful Websites

- `http://www.gnu.org/software/grub/` — The home page of the GNU GRUB project. This site contains information concerning the state of GRUB development and an FAQ.

- `http://kbase.redhat.com/faq/docs/DOC-6864` — Details booting operating systems other than Linux.
Appendix F. Boot Process, Init, and Shutdown

An important and powerful aspect of Fedora is the open, user-configurable method it uses for starting the operating system. Users are free to configure many aspects of the boot process, including specifying the programs launched at boot-time. Similarly, system shutdown gracefully terminates processes in an organized and configurable way, although customization of this process is rarely required.

Understanding how the boot and shutdown processes work not only allows customization, but also makes it easier to troubleshoot problems related to starting or shutting down the system.

F.1. The Boot Process

Below are the basic stages of the boot process for an x86 system:

1. The system BIOS checks the system and launches the first stage boot loader on the MBR of the primary hard disk.

2. The first stage boot loader loads itself into memory and launches the second stage boot loader from the /boot/ partition.

3. The second stage boot loader loads the kernel into memory, which in turn loads any necessary modules and mounts the root partition read-only.

4. The kernel transfers control of the boot process to the /sbin/init program.

5. The /sbin/init program loads all services and user-space tools, and mounts all partitions listed in /etc/fstab.

6. The user is presented with a login screen for the freshly booted Linux system.

Because configuration of the boot process is more common than the customization of the shutdown process, the remainder of this chapter discusses in detail how the boot process works and how it can be customized to suite specific needs.

F.2. A Detailed Look at the Boot Process

The beginning of the boot process varies depending on the hardware platform being used. However, once the kernel is found and loaded by the boot loader, the default boot process is identical across all architectures. This chapter focuses primarily on the x86 architecture.

F.2.1. The BIOS

When an x86 computer is booted, the processor looks at the end of system memory for the Basic Input/Output System or BIOS program and runs it. The BIOS controls not only the first step of the boot process, but also provides the lowest level interface to peripheral devices. For this reason it is written into read-only, permanent memory and is always available for use.

Other platforms use different programs to perform low-level tasks roughly equivalent to those of the BIOS on an x86 system.

Once loaded, the BIOS tests the system, looks for and checks peripherals, and then locates a valid device with which to boot the system. Usually, it checks any diskette drives and optical drives present
for bootable media, then, failing that, looks to the system's hard drives. In most cases, the order of the
drives searched while booting is controlled with a setting in the BIOS, and it looks on the master IDE
device on the primary IDE bus. The BIOS then loads into memory whatever program is residing in the
first sector of this device, called the Master Boot Record or MBR. The MBR is only 512 bytes in size
and contains machine code instructions for booting the machine, called a boot loader, along with the
partition table. Once the BIOS finds and loads the boot loader program into memory, it yields control of
the boot process to it.

F.2.2. The Boot Loader

This section looks at the default boot loader for the x86 platform, GRUB. Depending on the system's
architecture, the boot process may differ slightly. Refer to Section F.2.2.1, “Boot Loaders for Other
Architectures” for a brief overview of non-x86 boot loaders. For more information about configuring
and using GRUB, see Appendix E, The GRUB Boot Loader.

A boot loader for the x86 platform is broken into at least two stages. The first stage is a small machine
code binary on the MBR. Its sole job is to locate the second stage boot loader and load the first part of
it into memory.

GRUB has the advantage of being able to read ext2, ext3, and ext4 1 partitions and load its
configuration file — /boot/grub/grub.conf — at boot time. Refer to Section E.7, “GRUB Menu
Configuration File” for information on how to edit this file.

Important — Supported file systems

The GRUB bootloader in Fedora 14 supports ext2, ext3, and ext4 file systems. It does not
support other file systems such as VFAT, Btrfs or XFS. Furthermore, GRUB does not support
LVM.

Note

If upgrading the kernel using the Red Hat Update Agent, the boot loader configuration file is
updated automatically. More information on Red Hat Network can be found online at the following
URL: https://rhn.redhat.com/.

Once the second stage boot loader is in memory, it presents the user with a graphical screen showing
the different operating systems or kernels it has been configured to boot. On this screen a user can
use the arrow keys to choose which operating system or kernel they wish to boot and press Enter. If
no key is pressed, the boot loader loads the default selection after a configurable period of time has
passed.

Once the second stage boot loader has determined which kernel to boot, it locates the corresponding
kernel binary in the /boot/ directory. The kernel binary is named using the following format — /
boot/vmlinuz-<kernel-version> file (where <kernel-version> corresponds to the kernel
version specified in the boot loader's settings).

For instructions on using the boot loader to supply command line arguments to the kernel, refer to
Appendix E, The GRUB Boot Loader. For information on changing the runlevel at the boot loader
prompt, refer Section E.8, “Changing Runlevels at Boot Time”.

1 GRUB reads ext3 and ext4 file systems as ext2, disregarding the journal file.
The boot loader then places one or more appropriate initramfs images into memory. Next, the kernel decompresses these images from memory to /sysroot/, a RAM-based virtual file system, via cpio. The initramfs is used by the kernel to load drivers and modules necessary to boot the system. This is particularly important if SCSI hard drives are present or if the systems use the ext3 or ext4 file system.

Once the kernel and the initramfs image(s) are loaded into memory, the boot loader hands control of the boot process to the kernel.

For a more detailed overview of the GRUB boot loader, refer to Appendix E, The GRUB Boot Loader.

F.2.2.1. Boot Loaders for Other Architectures

Once the kernel loads and hands off the boot process to the init command, the same sequence of events occurs on every architecture. So the main difference between each architecture’s boot process is in the application used to find and load the kernel.

For example, the IBM eServer pSeries architecture uses yaboot, and the IBM System z systems use the z/IPL boot loader.

Consult the sections of this guide specific to these platforms for information on configuring their boot loaders.

F.2.3. The Kernel

When the kernel is loaded, it immediately initializes and configures the computer's memory and configures the various hardware attached to the system, including all processors, I/O subsystems, and storage devices. It then looks for the compressed initramfs image(s) in a predetermined location in memory, decompresses it directly to /sysroot/, and loads all necessary drivers. Next, it initializes virtual devices related to the file system, such as LVM or software RAID, before completing the initramfs processes and freeing up all the memory the disk image once occupied.

The kernel then creates a root device, mounts the root partition read-only, and frees any unused memory.

At this point, the kernel is loaded into memory and operational. However, since there are no user applications that allow meaningful input to the system, not much can be done with the system.

To set up the user environment, the kernel executes the /sbin/init program.

F.2.4. The /sbin/init Program

The /sbin/init program (also called init) coordinates the rest of the boot process and configures the environment for the user.

When the init command starts, it becomes the parent or grandparent of all of the processes that start up automatically on the system. First, it runs the /etc/rc.d/rc.sysinit script, which sets the environment path, starts swap, checks the file systems, and executes all other steps required for system initialization. For example, most systems use a clock, so rc.sysinit reads the /etc/sysconfig/clock configuration file to initialize the hardware clock. Another example is if there are special serial port processes which must be initialized, rc.sysinit executes the /etc/rc.serial file.

The init command then processes the jobs in the /etc/event.d directory, which describe how the system should be set up in each SysV init runlevel. Runlevels are a state, or mode, defined by the services listed in the SysV /etc/rc.d/rc<x>.d/ directory, where <x> is the number of the runlevel. For more information on SysV init runlevels, refer to Section F.4, “SysV Init Runlevels.”
Appendix F. Boot Process, Init, and Shutdown

Next, the `init` command sets the source function library, `/etc/rc.d/init.d/functions`, for the system, which configures how to start, kill, and determine the PID of a program.

The `init` program starts all of the background processes by looking in the appropriate `rc` directory for the runlevel specified as the default in `/etc/inittab`. The `rc` directories are numbered to correspond to the runlevel they represent. For instance, `/etc/rc.d/rc5.d/` is the directory for runlevel 5.

When booting to runlevel 5, the `init` program looks in the `/etc/rc.d/rc5.d/` directory to determine which processes to start and stop.

Below is an example listing of the `/etc/rc.d/rc5.d/` directory:

```
K05innd -> ../init.d/innd
K05saslauthd -> ../init.d/saslauthd
K10dc_server -> ../init.d/dc_server
K10psacct -> ../init.d/psacct
K10radiusd -> ../init.d/radiusd
K12dc_client -> ../init.d/dc_client
K12FreeWnn -> ../init.d/FreeWnn
K12mailman -> ../init.d/mailman
K12mysqlid -> ../init.d/mysqlid
K15httpd -> ../init.d/httpd
K20netdump-server -> ../init.d/netdump-server
K20rstatd -> ../init.d/rstatd
K20rusersd -> ../init.d/rusersd
K20rwhod -> ../init.d/rwhod
K24irda -> ../init.d/irda
K25squid -> ../init.d/squid
K28amd -> ../init.d/amd
K30spamassassin -> ../init.d/spamassassin
K34dhcrelay -> ../init.d/dhcrelay
K34ypasswdd -> ../init.d/ypasswdd
K35dhcpd -> ../init.d/dhcpd
K35smb -> ../init.d/smb
K35vncserver -> ../init.d/vncserver
K36lisa -> ../init.d/lisa
K45arpwatch -> ../init.d/arpwatch
K45named -> ../init.d/named
K46radvd -> ../init.d/radvd
K50netdump -> ../init.d/netdump
K50snmpd -> ../init.d/snmpd
K50snmptrapd -> ../init.d/snmptrapd
K50tux -> ../init.d/tux
K50vsftpd -> ../init.d/vsftpd
K54dovecot -> ../init.d/dovecot
K61ldap -> ../init.d/ldap
K65kadmin -> ../init.d/kadmin
K65kprop -> ../init.d/kprop
K65krb524 -> ../init.d/krb524
K65krb5kdc -> ../init.d/krb5kdc
K70aep1000 -> ../init.d/aep1000
K70bcm5820 -> ../init.d/bcm5820
K74yserv -> ../init.d/yserv
K74yxfrd -> ../init.d/yxfrd
K85mdmpd -> ../init.d/mdmpd
K89netplugd -> ../init.d/netplugd
K99microcode_ctl -> ../init.d/microcode_ctl
S04readahead_early -> ../init.d/readahead_early
S05kudzu -> ../init.d/kudzu
S06cpuspeed -> ../init.d/cpuspeed
S08iptables -> ../init.d/iptables
S08iptables -> ../init.d/iptables
S09isdn -> ../init.d/isdn
```
As illustrated in this listing, none of the scripts that actually start and stop the services are located in the `/etc/rc.d/rc5.d/` directory. Rather, all of the files in `/etc/rc.d/rc5.d/` are symbolic links pointing to scripts located in the `/etc/rc.d/init.d/` directory. Symbolic links are used in each of the rc directories so that the runlevels can be reconfigured by creating, modifying, and deleting the symbolic links without affecting the actual scripts they reference.

The name of each symbolic link begins with either a K or an S. The K links are processes that are killed on that runlevel, while those beginning with an S are started.

The `init` command first stops all of the K symbolic links in the directory by issuing the `/etc/rc.d/init.d/<command> stop` command, where `<command>` is the process to be killed. It then starts all of the S symbolic links by issuing `/etc/rc.d/init.d/<command> start`.

**Note**

After the system is finished booting, it is possible to log in as root and execute these same scripts to start and stop services. For instance, the command `/etc/rc.d/init.d/httpd stop` stops the Apache HTTP Server.

Each of the symbolic links are numbered to dictate start order. The order in which the services are started or stopped can be altered by changing this number. The lower the number, the earlier it is started. Symbolic links with the same number are started alphabetically.
Note

One of the last things the init program executes is the /etc/rc.d/rc.local file. This file is useful for system customization. Refer to Section F.3, “Running Additional Programs at Boot Time” for more information about using the rc.local file.

After the init command has progressed through the appropriate rc directory for the runlevel, Upstart forks an /sbin/mingetty process for each virtual console (login prompt) allocated to the runlevel by the job definition in the /etc/event.d directory. Runlevels 2 through 5 have all six virtual consoles, while runlevel 1 (single user mode) has one, and runlevels 0 and 6 have none. The /sbin/mingetty process opens communication pathways to tty devices, sets their modes, prints the login prompt, accepts the user's username and password, and initiates the login process.

In runlevel 5, Upstart runs a script called /etc/X11/prefdm. The prefdm script executes the preferred X display manager — gdm, kdm, or xdm, depending on the contents of the /etc/sysconfig/desktop file.

Once finished, the system operates on runlevel 5 and displays a login screen.

F.2.5. Job definitions

Previously, the sysvinit package provided the init daemon for the default configuration. When the system started, this init daemon ran the /etc/inittab script to start system processes defined for each runlevel. The default configuration now uses an event-driven init daemon provided by the Upstart package. Whenever particular events occur, the init daemon processes jobs stored in the /etc/event.d directory. The init daemon recognises the start of the system as such an event.

Each job typically specifies a program, and the events that trigger init to run or to stop the program. Some jobs are constructed as tasks, which perform actions and then terminate until another event triggers the job again. Other jobs are constructed as services, which init keeps running until another event (or the user) stops it.

For example, the /etc/events.d/tty2 job is a service to maintain a virtual terminal on tty2 from the time that the system starts until the system shuts down, or another event (such as a change in runlevel) stops the job. The job is constructed so that init will restart the virtual terminal if it stops unexpecedly during that time:

```bash
# tty2 - getty
#
# This service maintains a getty on tty2 from the point the system is
# started until it is shut down again.
start on stopped rc2
start on stopped rc3
start on stopped rc4
start on started prefdm
stop on runlevel 0
stop on runlevel 1
stop on runlevel 6
```

---

2 Refer to the Fedora Deployment Guide for more information about tty devices.
3 Refer to the Fedora Deployment Guide for more information about display managers.
F.3. Running Additional Programs at Boot Time

The `/etc/rc.d/rc.local` script is executed by the `init` command at boot time or when changing runlevels. Adding commands to the bottom of this script is an easy way to perform necessary tasks like starting special services or initialize devices without writing complex initialization scripts in the `/etc/rc.d/init.d/` directory and creating symbolic links.

The `/etc/rc.serial` script is used if serial ports must be setup at boot time. This script runs `setserial` commands to configure the system's serial ports. Refer to the `setserial` man page for more information.

F.4. SysV Init Runlevels

The SysV init runlevel system provides a standard process for controlling which programs `init` launches or halts when initializing a runlevel. SysV init was chosen because it is easier to use and more flexible than the traditional BSD-style init process.

The configuration files for SysV init are located in the `/etc/rc.d/` directory. Within this directory, are the `rc`, `rc.local`, `rc.sysinit`, and, optionally, the `rc.serial` scripts as well as the following directories:

```
```

The `init.d/` directory contains the scripts used by the `/sbin/init` command when controlling services. Each of the numbered directories represent the six runlevels configured by default under Fedora.

F.4.1. Runlevels

The idea behind SysV init runlevels revolves around the idea that different systems can be used in different ways. For example, a server runs more efficiently without the drag on system resources created by the X Window System. Or there may be times when a system administrator may need to operate the system at a lower runlevel to perform diagnostic tasks, like fixing disk corruption in runlevel 1.

The characteristics of a given runlevel determine which services are halted and started by `init`. For instance, runlevel 1 (single user mode) halts any network services, while runlevel 3 starts these services. By assigning specific services to be halted or started on a given runlevel, `init` can quickly change the mode of the machine without the user manually stopping and starting services.

The following runlevels are defined by default under Fedora:

- 0 — Halt
- 1 — Single-user text mode
- 2 — Not used (user-definable)
- 3 — Full multi-user text mode
- 4 — Not used (user-definable)
• 5 — Full multi-user graphical mode (with an X-based login screen)
• 6 — Reboot

In general, users operate Fedora at runlevel 3 or runlevel 5 — both full multi-user modes. Users sometimes customize runlevels 2 and 4 to meet specific needs, since they are not used.

The default runlevel for the system is listed in /etc/inittab. To find out the default runlevel for a system, look for the line similar to the following near the bottom of /etc/inittab:

id:5:initdefault:

The default runlevel listed in this example is five, as the number after the first colon indicates. To change it, edit /etc/inittab as root.

Warning

Be very careful when editing /etc/inittab. Simple typos can cause the system to become unbootable. If this happens, either use a boot diskette, enter single-user mode, or enter rescue mode to boot the computer and repair the file.

For more information on single-user and rescue mode, refer to the chapter titled Basic System Recovery in the Fedora Deployment Guide.

It is possible to change the default runlevel at boot time by modifying the arguments passed by the boot loader to the kernel. For information on changing the runlevel at boot time, refer to Section E.8, “Changing Runlevels at Boot Time”.

F.4.2. Runlevel Utilities

One of the best ways to configure runlevels is to use an initscript utility. These tools are designed to simplify the task of maintaining files in the SysV init directory hierarchy and relieves system administrators from having to directly manipulate the numerous symbolic links in the subdirectories of /etc/rc.d/.

Fedora provides three such utilities:

• /sbin/chkconfig — The /sbin/chkconfig utility is a simple command line tool for maintaining the /etc/rc.d/init.d/ directory hierarchy.

• /usr/sbin/ntsysv — The ncurses-based /sbin/ntsysv utility provides an interactive text-based interface, which some find easier to use than chkconfig.

• Services Configuration Tool — The graphical Services Configuration Tool (system-config-services) program is a flexible utility for configuring runlevels.

Refer to the chapter titled Controlling Access to Services in the Fedora Deployment Guide for more information regarding these tools.

F.5. Shutting Down

To shut down Fedora, the root user may issue the /sbin/shutdown command. The shutdown man page has a complete list of options, but the two most common uses are:
After shutting everything down, the `-h` option halts the machine, and the `-r` option reboots.

PAM console users can use the `reboot` and `halt` commands to shut down the system while in runlevels 1 through 5. For more information about PAM console users, refer to the Fedora Deployment Guide.

If the computer does not power itself down, be careful not to turn off the computer until a message appears indicating that the system is halted.

Failure to wait for this message can mean that not all the hard drive partitions are unmounted, which can lead to file system corruption.
Appendix G. Alternatives to busybox commands

Unlike previous releases of Fedora, Fedora 14 does not include a version of busybox to provide shell commands in the pre-installation and post-installation environments. Table G.1, "Alternatives to busybox commands" contains a list of busybox commands, equivalent ways to implement the same functionality in bash, and the availability of these alternatives in the %pre and %post environments. The table also indicates the exact path to the command, although you do not generally need to specify the path because the PATH environment variable is set in the installation environment.

If a command is only available in %post, the command is running on the target system and its availability therefore depends on whether the package that provides the command is installed. Every command that appears in the "New command or alternative" column of Table G.1, "Alternatives to busybox commands" is available for Fedora 14, although not every command is available on every installed system.

Where a command is listed as unavailable, you might be able to create equivalent functionality with a Python script. The Python language is available to %pre and %post script authors, complete with a set of Python modules ready for use. Therefore, if a particular command is not available to you in the installation environment, we recommend that you use Python as the script language.

</tbody>
</table>

1. Fedora 14 ships with GNU `awk` rather than the busybox `awk` in the installation environment.
2. GNU bash can provide basename functionality using string manipulation. If `var="/usr/bin/command"`, then `echo ${var##*/}` gives `command`.
3. GNU bash can provide dirname functionality using string manipulation. If `var="/usr/bin/command"`, then `echo ${var%/}*` gives `/usr/bin`. 
Appendix H. Other Technical Documentation

To learn more about anaconda, the Fedora installation program, visit the project Web page: http://www.fedoraproject.org/wiki/Anaconda.

Both anaconda and Fedora systems use a common set of software components. For detailed information on key technologies, refer to the Web sites listed below:

Boot Loader
Fedora uses the GRUB boot loader. Refer to http://www.gnu.org/software/grub/ for more information.

Disk Partitioning
Fedora uses parted to partition disks. Refer to http://www.gnu.org/software/parted/ for more information.

Storage Management
Logical Volume Management (LVM) provides administrators with a range of facilities to manage storage. By default, the Fedora installation process formats drives as LVM volumes. Refer to http://www.tldp.org/HOWTO/LVM-HOWTO/ for more information.

Audio Support
The Linux kernel used by Fedora incorporates PulseAudio audio server. For more information about PulseAudio, refer to the project documentation: http://www.pulseaudio.org/wiki/Documentation.

Graphics System
Both the installation system and Fedora use the Xorg suite to provide graphical capabilities. Components of Xorg manage the display, keyboard and mouse for the desktop environments that users interact with. Refer to http://www.x.org/ for more information.

Remote Displays
Fedora and anaconda include VNC (Virtual Network Computing) software to enable remote access to graphical displays. For more information about VNC, refer to the documentation on the RealVNC Web site: http://www.realvnc.com/documentation.html.

Command-line Interface
By default, Fedora uses the GNU bash shell to provide a command-line interface. The GNU Core Utilities complete the command-line environment. Refer to http://www.gnu.org/software/bash/bash.html for more information on bash. To learn more about the GNU Core Utilities, refer to http://www.gnu.org/software/coreutils/.

Remote System Access
Fedora incorporates the OpenSSH suite to provide remote access to the system. The SSH service enables a number of functions, which include access to the command-line from other systems, remote command execution, and network file transfers. During the installation process anaconda may use the scp
feature of OpenSSH to transfer crash reports to remote systems. Refer to the OpenSSH Web site for more information: http://www.openssh.com/.

Access Control

SELinux provides Mandatory Access Control (MAC) capabilities that supplement the standard Linux security features. Refer to the SELinux Project Pages for more information: http://docs.fedoraproject.org/selinux-guide.

Firewall

The Linux kernel used by Fedora incorporates the netfilter framework to provide firewall features. The Netfilter project website provides documentation for both netfilter, and the iptables administration facilities: http://netfilter.org/documentation/index.html.

Software Installation

Fedora uses yum to manage the RPM packages that make up the system. Refer to http://docs.fedoraproject.org/yum/ for more information.

Virtualization

Virtualization provides the capability to simultaneously run multiple operating systems on the same computer. Fedora also includes tools to install and manage the secondary systems on a Fedora host. You may select virtualization support during the installation process, or at any time thereafter. Refer to the Fedora Virtualization Guide available from http://docs.fedoraproject.org/ for more information.

http://docs.fedoraproject.org/install-guide/

I.2. Production methods

Writers produce the Install Guide directly in DocBook XML in a revision control repository. They collaborate with other subject matter experts during the beta release phase of Fedora to explain the installation process. The editorial team ensures consistency and quality of the finished guide. At this point, the team of translators produces other language versions of the release notes, and then they become available to the general public as part of Fedora. The publication team also makes the guide, and subsequent errata, available via the Web.
